1. Abstract

NOAA Atlas 14 contains precipitation frequency estimates for the United States and U.S. affiliated territories with associated 90% confidence intervals and supplementary information on temporal distribution of annual maxima, analysis of seasonality and trends in annual maximum series data, etc. It includes pertinent information on development methodologies and intermediate results. The results are published through the Precipitation Frequency Data Server (http://hdsc.nws.noaa.gov/hdsc/pfds).

The Atlas is divided into volumes based on geographic sections of the country. The Atlas is intended as the U.S. Government source of precipitation frequency estimates and associated information for the United States and U.S. affiliated territories.

2. Preface to Volume 6

NOAA Atlas 14 Volume 6 contains precipitation frequency estimates for selected durations and frequencies with 90% confidence intervals and supplementary information on temporal distribution of annual maxima, analysis of seasonality and trends in annual maximum series data, etc., for the state of California. The results are published through the Precipitation Frequency Data Server (http://hdsc.nws.noaa.gov/hdsc/pfds).

NOAA Atlas 14 Volume 6 was developed by the Hydrometeorological Design Studies Center within the Office of Hydrologic Development of the National Oceanic and Atmospheric Administration's National Weather Service. Any use of trade names in this publication is for descriptive purposes only and does not imply endorsement by the U.S. Government.

Citation and version history. This documentation and associated artifacts such as maps, grids, and point-and-click results from the PFDS are part of a whole with a single version number and can be referenced as:

Sanja Perica, Sarah Dietz, Sarah Heim, Lillian Hiner, Kazungu Maitaria, Deborah Martin, Sandra Pavlovic, Ishani Roy, Carl Trypaluk, Dale Unruh, Fenglin Yan, Michael Yekta, Tan Zhao, Geoffrey Bonnin, Daniel Brewer, Li-Chuan Chen, Tye Parzybok, John Yarchoan (2011). NOAA Atlas 14 Volume 6 Version 2.0, *Precipitation-Frequency Atlas of the United States, California*. NOAA, National Weather Service, Silver Spring, MD.

The version number has the format P.S where P is a primary version number representing a number of successive releases of primary information. Primary information is essentially the data. S is a secondary version number representing successive releases of secondary information. Secondary information includes documentation and metadata. S reverts to zero (or nothing; i.e., Version 2 and Version 2.0 are equivalent) when P is incremented. When new information is completed and added (such as draft documentation) without changing any prior information, the version number is not incremented.

The primary version number is stamped on the artifact or is included as part of the filename where the format does not allow for a version stamp (for example, files with gridded precipitation frequency estimates). All location-specific output from the PFDS is stamped with the version number and date of download.

Table 2.1 lists the version history associated with the NOAA Atlas 14 Volume 6 precipitation frequency project and indicates the nature of changes made.

Table 2.1. Version history of NOAA Atlas 14, Volume 6.

Version no.	**Date**	**Notes**
Version 1.0	July 2010	Draft data used in peer review
Version 2.0	April 2011	Final data released
Version 2.1	December 2012	Paragraph in documentation on areal reduction factors edited
Version 2.2	September 2013	Paragraphs in documentation on development of sub-hourly estimates edited
Version 2.3	January 2014	Seasonality graphs under supplementary information edited

3. Introduction

3.1. Objective

NOAA Atlas 14 Volume 6 provides precipitation frequency estimates for the state of California. The Atlas provides precipitation frequency estimates for 5-minute through 60-day durations at average recurrence intervals of 1-year through 1,000-year. The estimates and associated bounds of 90% confidence intervals are provided at 30-arc seconds resolution. The Atlas also includes information on temporal distributions and seasonal information for annual maxima data used in frequency analysis. In addition, the potential effects of climate change as trends in historic annual maximum series were examined.

The information in NOAA Atlas 14 Volume 6 supersedes precipitation frequency estimates for California contained in the following publications:

a. *NOAA Atlas 14 Volume 1, Precipitation-Frequency Atlas of the United States, Semiarid Southwest* (Bonnin et al., 2004);
b. *Short Duration Rainfall Frequency Relations for California* (Frederick and Miller, 1979);
c. *NOAA Atlas 2 Volume 11, Precipitation Frequency Atlas of the Western United States, California* (Miller et al., 1973);
d. *Technical Paper No. 49, Two- to Ten-Day Precipitation for Return Periods of 2 to 100 Years in the Contiguous United States* (Miller, 1964).

3.2. Approach and deliverables

Precipitation frequency estimates have been computed for a range of frequencies and durations using a regional frequency analysis approach based on L-moment statistics calculated from annual maximum series. This section provides an overview of the approach; greater detail is provided in Section 4.

The annual maximum series were extracted from precipitation measurements recorded at variable or constant time increments from 1-minute to 1-day obtained from various sources. The table in Appendix A.1 gives detailed information on all stations whose data were used in the frequency analysis. The annual maximum series data were screened for erroneous measurements. The 1-day and 1-hour annual maximum series data were also analyzed for potential trends (Appendix A.2).

A region of influence approach was used for the regional L-moments computation at each station across all durations. A variety of probability distribution functions were examined for each region and duration and the most suitable distribution was selected. Distribution parameters, and consequently precipitation frequency estimates, were determined based on the mean of the annual maximum series at the station and the regionally determined higher order L-moments for each duration. Higher order L-moments were smoothed across durations to ensure consistency in precipitation frequency estimates. L-moments for all stations across all durations are listed in Appendix A.3. Partial duration series-based precipitation frequency estimates were calculated indirectly using Langbein's formula.

Empirical equations were developed to estimate frequency estimates for rainfall (i.e., liquid precipitation only) from corresponding precipitation frequency estimates for selected durations up to 24-hours.

A Monte-Carlo simulation approach was used to produce upper and lower bounds of the 90% confidence intervals for the precipitation frequency estimates. Due to the small number of stations recording precipitation at sub-hourly intervals, precipitation frequency estimates and confidence

intervals for sub-hourly durations were computed by applying scaling factors to corresponding estimates at the shortest duration for which measurements were available.

Grids of precipitation frequency estimates and 90% confidence intervals were determined based on mean annual maxima grids and at-station precipitation frequency estimates. The mean annual maxima grid for each duration was derived from at-station mean annual maxima using PRISM interpolation methodology (Appendix A.4). The grids of precipitation frequency estimates and confidence limits for all frequencies were then derived in an iterative process using the Cascade, Residual Add-Back (CRAB) spatial interpolation procedure. The resulting grids were examined and adjusted in cases where inconsistencies occurred between durations and frequencies. Both spatially interpolated and point estimates at selected durations and frequencies were subject to external peer review (Appendix A.5).

Climate regions were delineated based on characteristics of annual maxima data and used in calculations of temporal distributions and seasonality analysis of annual maxima for selected durations. The temporal distributions were computed for each region. They are expressed in probability terms as cumulative percentages of precipitation totals at various time steps (Appendix A.6). The seasonality analysis was done by tabulating the number of annual maxima exceeding precipitation frequency estimates for several selected threshold frequencies in each climate region (Appendix A.7).

NOAA Atlas 14 Volume 6 precipitation frequency estimates for any location in the project area are available in a variety of formats through the Precipitation Frequency Data Server (PFDS) at http://hdsc.nws.noaa.gov/hdsc/pfds (via a point-and-click interface); more details are provided in Section 5. Additional types of results and information available there include:

- ASCII grids of partial duration series-based and annual maximum series-based precipitation frequency estimates and related confidence intervals for a range of durations and frequencies with associated Federal Geographic Data Committee-compliant metadata;
- ASCII grids of partial duration series-based and annual maximum series-based rainfall frequency estimates and associated confidence intervals for a range of frequencies and durations up to 24 hours;
- cartographic maps of partial duration series-based precipitation frequency estimates for selected frequencies and durations;
- annual maximum series used in the analysis;
- temporal distributions;
- seasonality analysis of annual maxima.

Cartographic maps were created to serve as visual aids and are not recommended for estimating precipitation frequency estimates. Users are advised to take advantage of the PFDS interface or the underlying ASCII grids for obtaining precipitation frequency estimates. Precipitation frequency estimates from this Atlas are estimates for a point location and are not directly applicable for an area.

4. Frequency analysis

4.1. Project area

The project area, shown in Figure 4.1.1, encompasses the entire state of California including the southeast semiarid area previously published in NOAA Atlas 14 Volume 1 (shown in figure as the area filled with a horizontal line pattern). The terrain and climates in California are highly varied. California is the home to both the highest (Mt. Whitney) and lowest (Death Valley) points in the contiguous United States. Several mountain ranges dominate the geography. Running parallel to the coast is a Coastal Range with peak elevations above 8,000 feet (2,438 meters). In the north, the Coastal Range merges with the Cascade Range further inland. The Cascades then extend southeastward until they merge into the Sierra Nevada Range which runs parallel to the Coastal Range. Some Sierra Nevada peaks are more than 10,000 feet (3,050 meters) in the south with Mount Whitney at 14,505 feet (4,421 meters). Between the Coastal and Sierra Nevada Ranges is the flat Central Valley averaging 45 miles (72 kilometers) in width. The Central Valley is actually composed of two valleys: the Sacramento Valley to the north and the San Joaquin Valley to the south. The Tehachapi Mountains extend southwestward along the southern end of the Central Valley to merge with the Coastal Range. Further south a series of ranges encircle the LA Basin and also separate a maritime climate to the west and the Mojave Desert to the east. Death Valley in the desert is the lowest area in the North America with elevations going down to 282 feet (86 meters) below sea level.

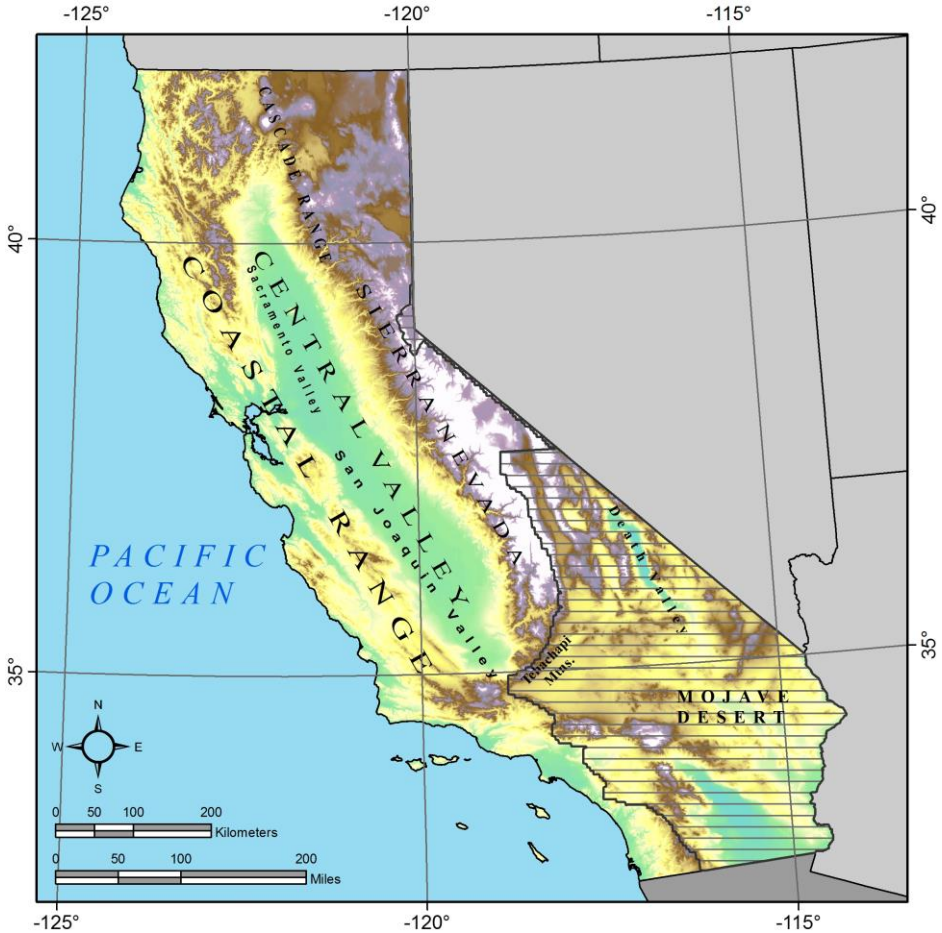

Figure 4.1.1. Project area for NOAA Atlas 14 Volume 6.

Climatology of heavy precipitation. The climate of California is as diverse as its geography: from hot, dry desserts to cold, wet mountain peaks. The seasonal distribution of heavy precipitation is driven by a large area of high pressure that resides over the northeastern Pacific Ocean during the summer months and moves south during the winter months. In the summer, this area of high pressure prevents mid-latitude cyclones from bringing rainfall to much of California. However, during the summer and fall, southern California can be susceptible to the remnants of tropical cyclones which can bring copious amounts of rainfall, although there is no record of an actual hurricane making landfall. During the winter, the high pressure withdraws to the south allowing maritime storms to progress into California, especially over northern portions of the state. Occasionally, a large-scale trough will also allow a series of low-pressure systems to move through the state causing severe inundation. Most extreme precipitation events occur during the winter months.

As moisture-laden storms reach the shoreline, precipitation is orographically enhanced by the western facing Coastal Range Mountains. Beyond these mountains, the low-lying interior Central Valley region is cut off from the maritime moisture and receives much less precipitation. Continuing farther inland to the east, the Sierra Nevada causes a second area of higher extreme precipitation. The Cascade Range, Sierra Nevada and LA Basin mountains serve to cut off moisture to eastern California forming a very dry, desert climate, particularly in the southeast. However, the southeastern desert region is susceptible to the Mexican Monsoons during the summer months where tropical Pacific moisture flows up from the southwest triggering brief but heavy downpours especially at higher elevations.

Fourteen climate regions were delineated and used in portraying the temporal distributions and seasonality of annual maxima data used in the precipitation frequency analysis. The climate regions together with the temporal distribution analysis are described in more detail in Appendix A.6. More details on seasonality analysis are available from Appendix A.7.

4.2. Precipitation data collection and formatting

Precipitation measurements were obtained for 8,278 stations from a number of federal, state, and county agencies, as well as from private citizens. The majority of the stations were from the National Weather Service (NWS) Cooperative Observer Program's database maintained by the National Oceanic and Atmospheric Administration's (NOAA) National Climatic Data Center (NCDC). Each station used in the project was assigned a unique six digits identification number (station ID), where first two digits were common for all stations from the same data provider. Except for NCDC stations, assigned identification numbers do not match identification numbers assigned by agencies that provided the data. A list of all agencies and individuals that provided the data for this project together with the abbreviated names (used in Appendix A.1 which lists all stations used in the analysis) and the common digits of identification numbers for all data sources are shown in Table 4.2.1.

Data came in various formats and were reported at variable or constant time increments from 1-minute to 1-day. Where available, records extended through May 2010. All data were formatted to a common format as one of three base durations that corresponded to the original reporting period: 15-minute, 1-hour, or 1-day. Data reported at intervals shorter than 15-minutes were aggregated to 15-minute increments. CNRFC's 6-hour data were aggregated to 1-day. ALERT data from various local districts reported at variable time intervals and were formatted to all three base durations to avoid loosing information due to distributing values into smaller increments. Table 4.2.2 lists the total number of stations that were obtained and formatted for each reporting interval.

Table 4.2.1. Agencies and individuals that provided data for the project with their abbreviated names and common first two digits of station identification numbers.

Data provider's name	Abbreviation	Common digits of station ID
Alameda County Flood Control District	ALAMEDA COUNTY	81
California Nevada River Forecast Center	CNRFC	96
California Department of Water Resources	DWR	95

Table 4.2.2. The number of stations that were obtained per reporting interval and per base duration to which the data were formatted.

Data reporting interval	Number of stations	Shortest duration after formatting	Number of stations
1-day	4,776	1-day	5426
6-hour	650		
1-hour	2,000	1-hour	2,000
15-minute	435	15-minute	852
5-minute	79		
1-minute	31		
Variable (ALERT)	307		

4.3. Annual maximum series extraction

The precipitation frequency analysis approach used in this project is based on analysis of annual maximum series (AMS) data across a range of durations. Annual maximum series for each station were obtained by extracting the highest precipitation amount for a particular duration in each successive water year (starting on October 1 of the previous calendar year and ending on September 30). The AMS at stations were extracted for all durations equal to and longer than the base duration to which the data were formatted (up to 60 days). AMS for the 1-day through 60-day durations were compiled from daily, hourly and 15-minute records. To accomplish this, hourly and 15-minute data were first aggregated to constrained 1-day (hours 0 to 24) values before extracting 1-day and longer duration annual maxima. Hourly and 15-minute data were used to compile AMS for 1-hour through 12-hour durations. Again, 15-minute data were aggregated to constrained 1-hour (0 to 60 minutes) values before extracting AMS. 15-minute data were also used to compile AMS for 15-minute and 30-minute durations.

The procedure for developing an AMS from a precipitation dataset used specific criteria designed to extract only reasonable maxima if a year was incomplete or had accumulated data. Accumulated data occurred in some records where observations were not taken regularly, so recorded numbers represent accumulated amounts over extended periods of time. Since the precipitation distribution over the period is unknown, the total amount was distributed uniformly across the whole period. All annual maxima that resulted from accumulated data were flagged and went through additional screening to ensure that the incomplete data did not result in erroneously low maxima (Section 4.5.1).

The criteria for AMS extraction were designed to exclude maxima if there were too many missing or accumulated data during the year and more specifically during critical months when precipitation maxima were most likely to occur ("wet season"). Regions were delineated to depict wet seasons by inspecting histograms of annual maxima for the 1-day and 1-hour durations and by assessing the periods in which two-thirds of annual maxima occurred at each station. The final wet season months were allocated using the general wet season regions as depicted in Figure 4.3.1. The wet season months indicated in the figure were assigned to each station in the region.

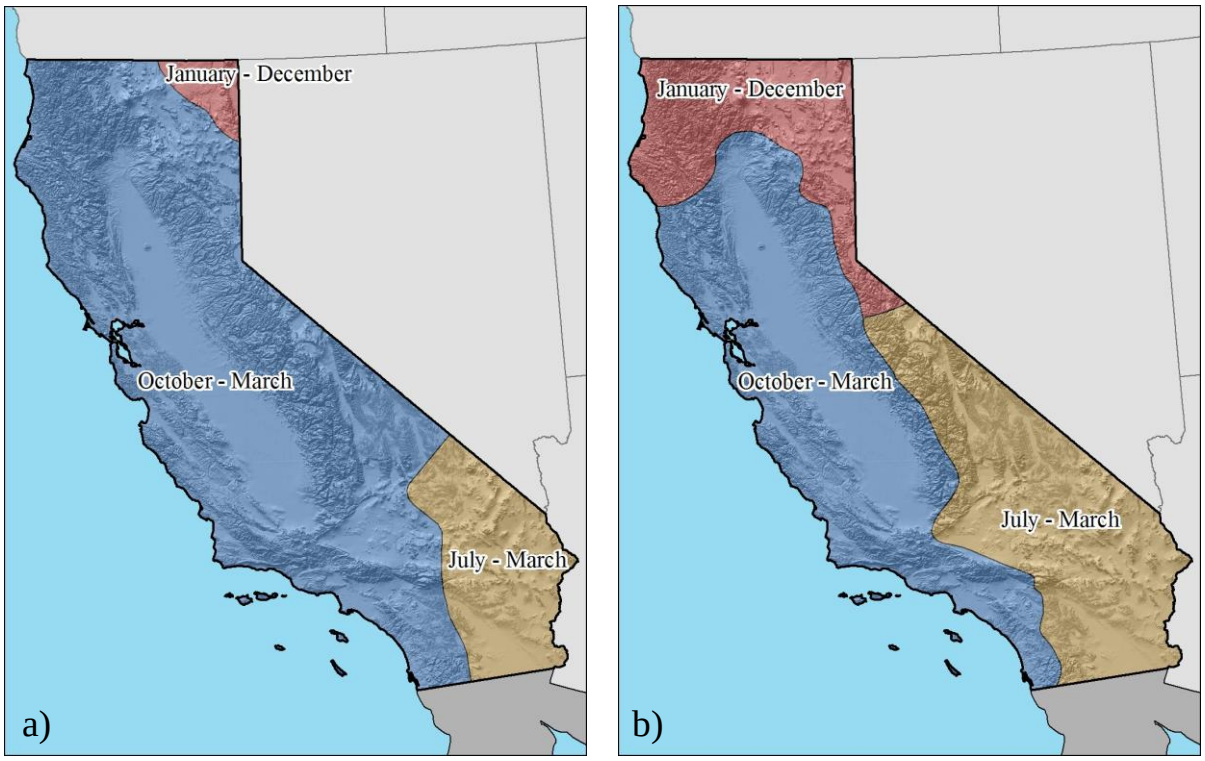

Figure 4.3.1.Wet season designations for a) daily durations; and b) sub-daily durations.

The flowchart in Figure 4.3.2 depicts the AMS extraction criteria for all durations. Various thresholds for acceptable amounts of missing or accumulated data were applied to the year and wet season. The extracted maximum value for a given year had to pass through all of the criteria in the flowchart to be accepted. For example, in a year with less than 20% of measurements missing in the whole year and during the assigned wet season, if more than 66% of measurements were accumulated, then the maxima for that year for that duration was (conditionally) rejected. If the year had between 33% and 66% accumulated data, then it was further screened by assessing the lengths of the accumulated periods. If accumulation periods for more than 33% of the accumulated data were equal to or longer than threshold accumulation period lengths (D_{thresh}), a maximum for that year was rejected. Threshold accumulation period lengths matched the selected duration for durations less than 2 days, were equal to half of duration period for durations between 2 days and 20 days, and were equal 15 days for durations equal to or longer than 30 days. If the year had less than 33% accumulated data, the extracted maximum was passed to another set of criteria for accumulations during its wet season, etc.

If a rejected annual maximum was higher than 95% of the accepted maxima at that station, then it was kept in the series. Also, if a rejected 1-day annual maximum was higher than any accumulated amount in a year, then it was kept in the series. Various codes were assigned to both, accepted and rejected maxima, based on the amount of missing and accumulated data in each year (see Figure 4.3.2) to assist in further quality control of AMS described in Section 4.5.1.

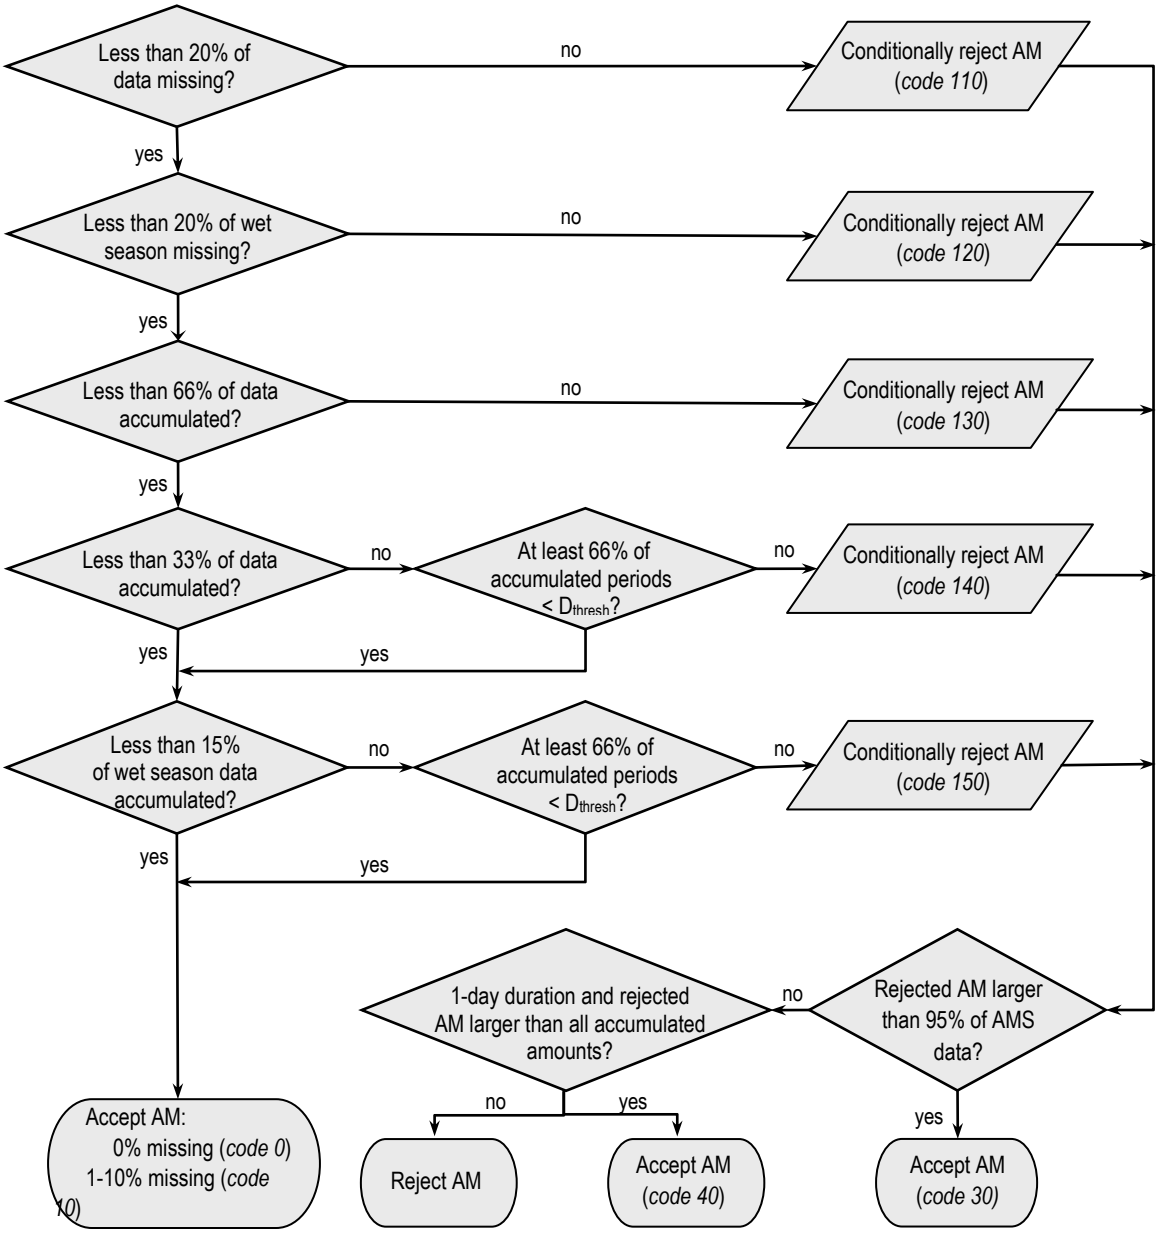

Figure 4.3.2. Flowchart of criteria used to extract annual maxima. Data quality codes were assigned based on acceptance and rejection. D_{thresh} depends on duration.

4.4. Station screening

Station screening was done in the following order: a) examination of geospatial data, b) screening for duplicate stations, c) screening for duplicate records at co-located daily, hourly, and/or 15-minute stations and extending records using data from co-located stations, c) screening nearby stations for

potentially merging records or removing shorter, less reliable records in station dense areas, and d) screening for sufficient number of years with usable data.

Geospatial data. Latitude, longitude, and elevation data for all stations were screened for errors. Several stations had to be re-located because they plotted in the ocean or were clearly misplaced based on inspection of satellite images and maps. Misplacement was typically the result of no seconds recorded in latitude and longitude data. There were also several stations with no elevation data; for those stations, elevation was estimated from high-resolution digital elevation model (DEM) grids.

Duplicate stations. In many instances, the same station was reported by more than one source. For example, a majority of the Department of Water Resources stations were also included in the State Climatologist dataset. Duplicate stations were screened from the final dataset.

Co-located stations. Co-located stations were defined as stations that have the same geospatial data, but report precipitation amounts at different time intervals. The screening of co-located stations was done as follows:

- If co-located 15-minute and hourly stations provided data for the same period and there were no differences in AMS for constrained 1-hour maxima (15-minute data aggregated based on the clock hour), only the 15-minute station was retained and used to extract AMS for all longer durations.
- If a 15-minute or hourly station provided data for the same period as a co-located daily station and there were no differences in AMS for constrained 1-day maxima (15-minute or 1-hour data aggregated from 0 to 24 hours), only the 15-minute or hourly station was retained and used to extract AMS for all longer durations.
- If periods of record at co-located stations were consistent but did not completely overlap, aggregated data from the station with the shorter reporting interval were used to extend the record of the station with the longer reporting interval.
- If the station with the longer reporting interval had a longer period of record, then it was retained in the dataset in addition to the co-located station with the shorter reporting interval.

AMS data consistency across durations was ensured in later quality control procedures (see Section 4.5.3).

Nearby stations. Nearby stations were defined as stations located within 3 miles with consideration to elevation differences. Their records were considered for merging to increase record lengths. Double-mass curve analysis and *t*-tests at the 90% confidence level were used to ensure that the annual maximum series of merged stations were from the same population. In station-dense areas, such as Los Angeles County, some stations were removed from the analysis if a nearby station had a longer record or better quality data.

Record length. Record length is characterized by the number of years for which annual maxima could be extracted (i.e., data years) rather than the entire period of record. Generally, only stations with at least 20 data years were used in frequency analysis. In regions with a dense station network, a minimum of 30 years was applied. Allowances were made for isolated stations.

Figure 4.4.1 shows histograms for the number of stations available for frequency analysis for daily, hourly and sub-hourly durations after all the screenings were done. The average and median record lengths as well as corresponding ranges of record lengths for these stations are given in Table 4.4.1.

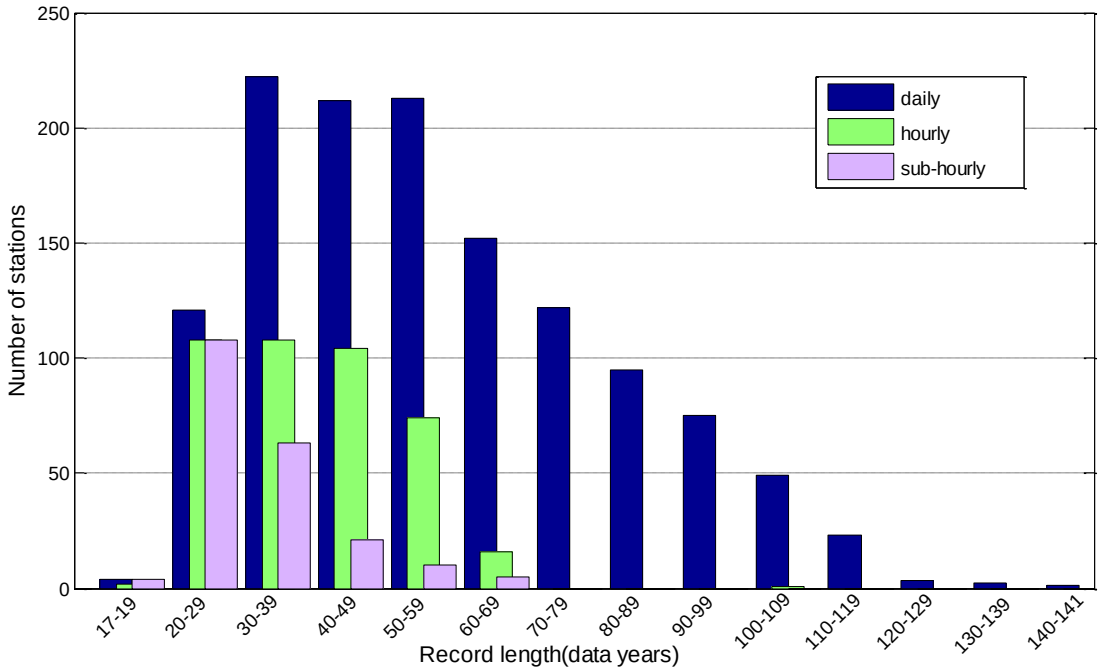

Figure 4.4.1. Number of stations used for precipitation frequency analysis grouped by record length for daily, hourly and sub-hourly durations.

Table 4.4.1. Record length statistics for stations used in frequency analysis for different durations.

Duration (D)	**Number of stations**	**Record length (data years)**		
		average	**median**	**range**
Daily (1-day ≤ D ≤ 60-day)	1,294	57	53	17 – 141
Hourly (1-hr ≤ D < 24-hr)	413	39	37	17 – 101
Sub-hourly (15-min ≤ D < 60-min)	211	31	29	17 – 66

Locations of stations recording precipitation data at 1-day intervals that were used in the frequency analysis are shown in Figure 4.4.2 and locations of hourly and sub-hourly stations are shown in Figure 4.4.3. More detailed information on each station whose data was used to calculate precipitation frequency estimates is given in three tables in Appendix A.1. The first table in the appendix lists stations in California. The second table lists stations in neighboring states at the border with California that were used in the analysis. The third table lists n-minute stations that were not directly used in frequency analysis but assisted in calculation of estimates at very short durations (see Section 4.6.3). Information provided for each station includes: source, name, identification number and data reporting interval, as well as latitude, longitude, elevation, and period of record. All adjusted geospatial data are shown in bold font in the latitude, longitude, and/or elevation columns. Bold font in the period of record column was also used to identify stations whose records were extended with the data from co-located stations or whose records were lengthened by merging with another station. The metadata from the station listed as the 'Post-merge station ID' was retained in the dataset for the merged record; the metadata for this station will reflect the combined periods of records in bold text.

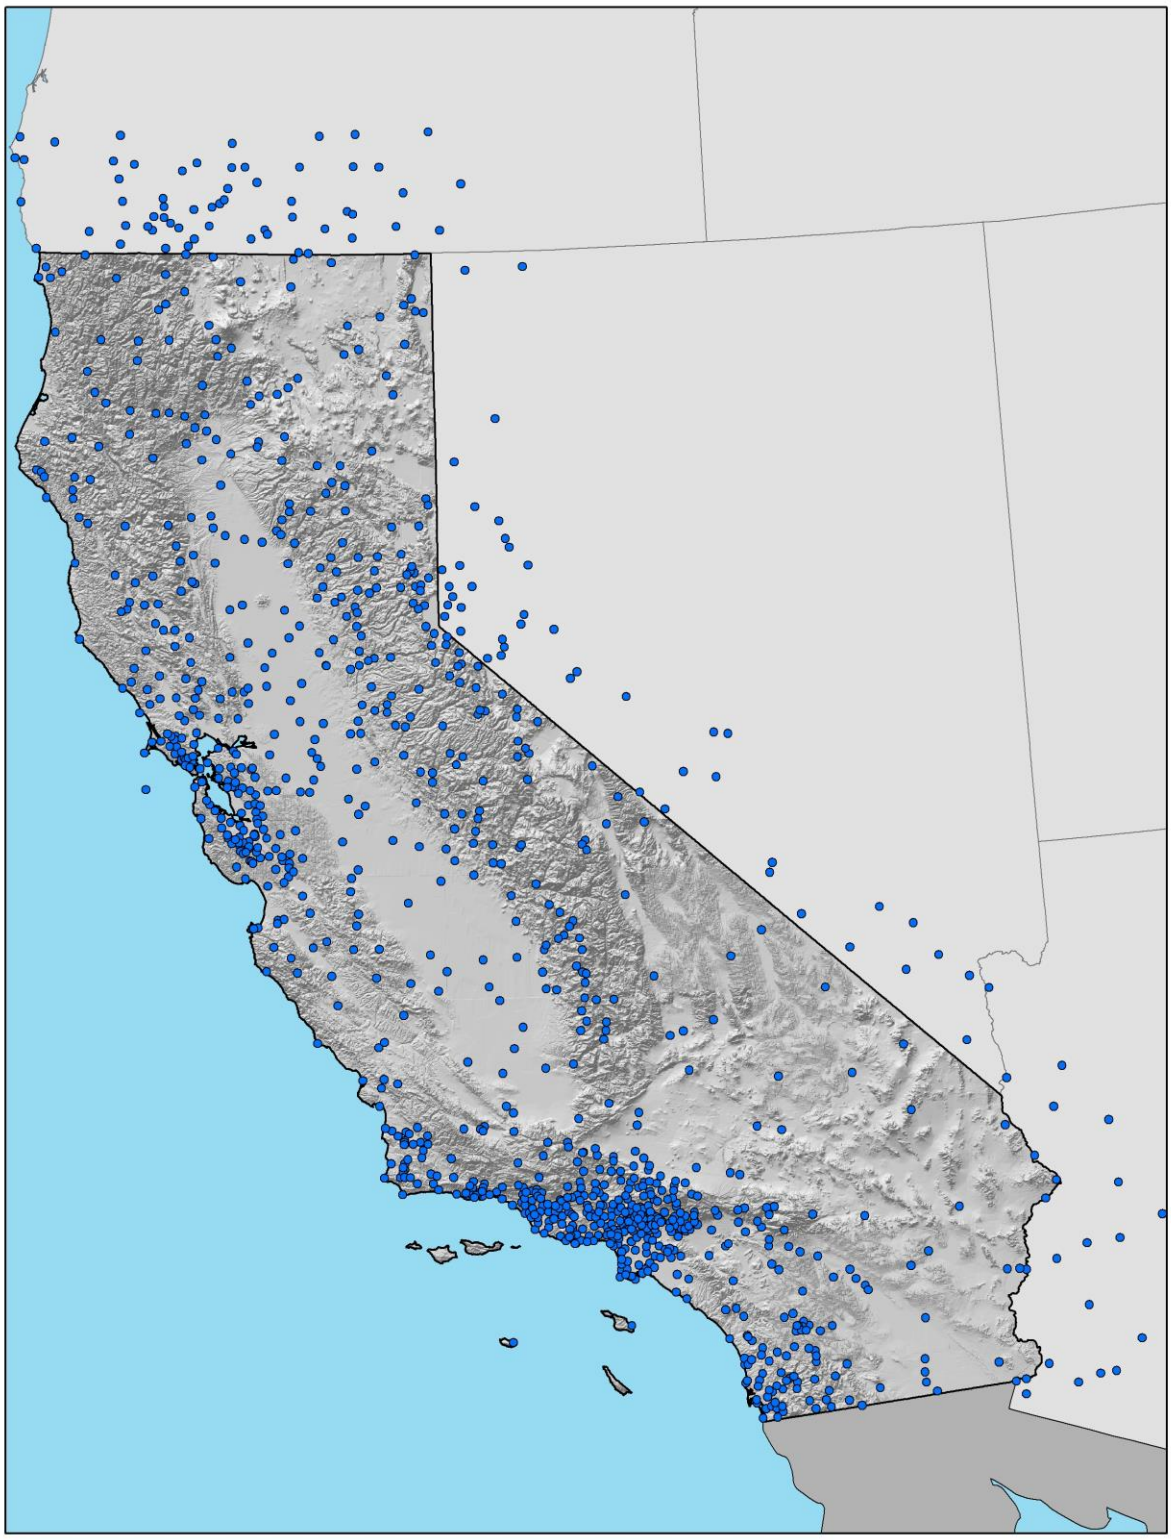

Figure 4.4.2. Map of stations recording at 1-day intervals used in frequency analysis.

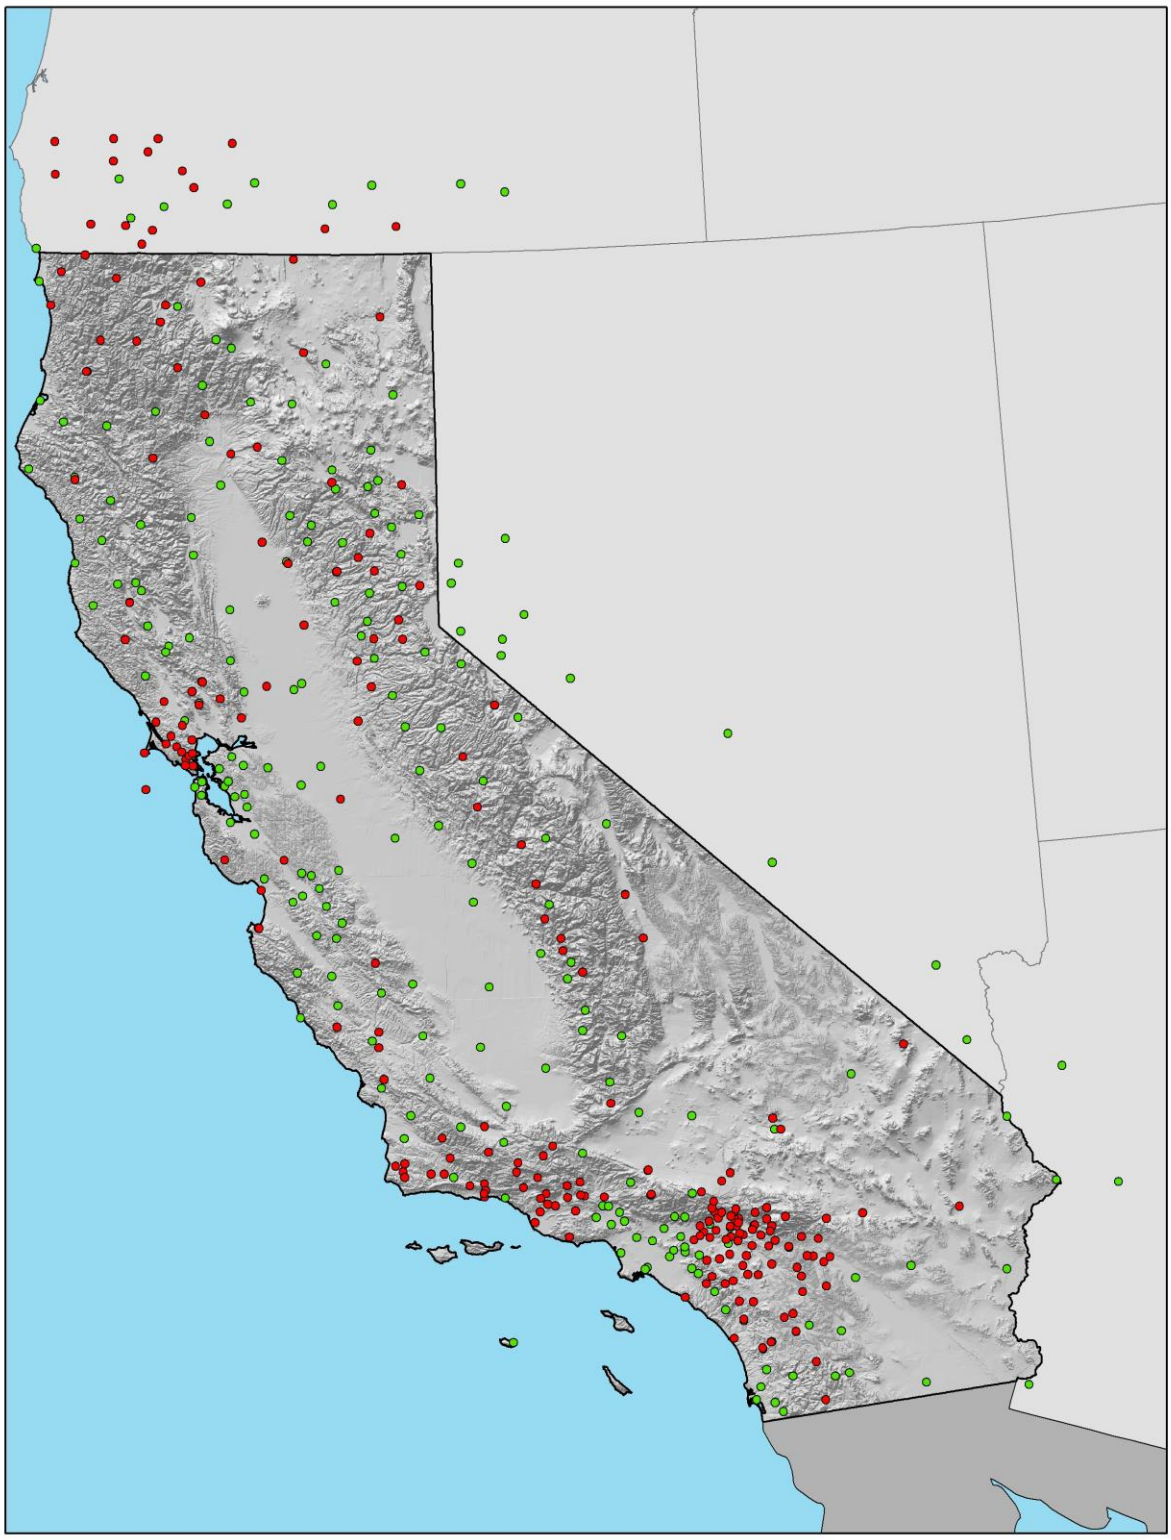

Figure 4.4.3. Map of stations recording at 1-hour (green dots) and sub-hourly or variable intervals (red dots) used in frequency analysis.

4.5. AMS screening and quality control

4.5.1. Outliers

For this project, outliers are defined as annual maxima which depart significantly from the trend of the corresponding remaining maxima. Since data at both high and low extremities can considerably affect precipitation frequency estimates, they have to be carefully investigated and either corrected or removed from the AMS if due to measurement errors. The Grubbs-Beck statistical test for outliers (Interagency Advisory Committee on Water Data, 1982) and the median +/- two standard deviations thresholds were used to identify low and high outliers for all durations (see an example of outlier examination in Figure 4.5.1). Low outliers which frequently came from years with missing and/or accumulated data were presumed untrue maxima and removed from the datasets. All values identified as high outliers were mapped with concurrent measurements at nearby stations. Questionable values that could not be confirmed by measurements at nearby stations were investigated further using climatological observation forms, monthly storm data reports and other historical weather events publications. Depending on the outcome of each investigation, values were either kept as is, corrected, or removed from the datasets. For example, the 1-day amount recorded on October 13, 1962 at station 04-1912, Colfax, CA, identified as a high outlier (as shown in Figure 4.5.1), was confirmed and kept in the dataset.

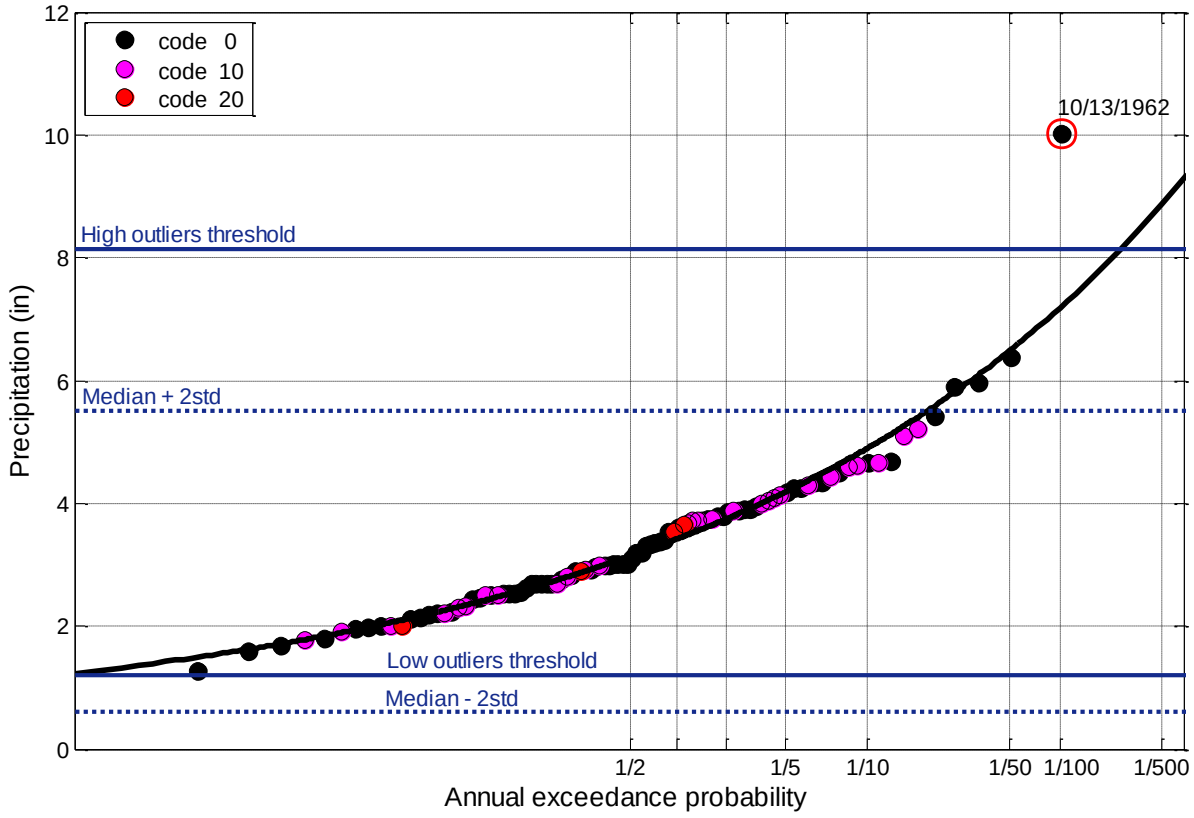

Figure 4.5.1. Outlier examination of 1-day AMS at station 04-1912. Data quality codes were assigned to all annual maxima during the extraction process (Section 4.3).

4.5.2. Correction for constrained observations

Daily durations. The majority of daily AMS data used in this project came from daily stations at which readings were taken once every day at fixed times (constrained observations). Due to the fixed beginning and ending of observation times at daily stations, it is likely that extracted (constrained) annual maxima were lower than the true (unconstrained) maxima, especially for shorter daily durations. To account for the likely failure of capturing the true-interval maxima, correction factors were applied to constrained AMS. Slope coefficients of zero-intercept regression models of concurrent (occurring within +/- 1 day) unconstrained and constrained annual maxima for a given duration at co-located stations were used to estimate correction factors. Correction factors for all daily durations are given in Table 4.5.1.

Table 4.5.1. Correction factors applied to constrained AMS data across daily durations.

Duration (days)	1	2	3	4	7	>7
Correction factor	1.13	1.05	1.04	1.03	1.02	1.00

Hourly durations. Similar adjustment was needed on hourly AMS data to account for the effects of constrained 'clock hour' on observations. Correction factors applied to hourly AMS are given in Table 4.5.2.

Table 4.5.2. Correction factors applied to constrained AMS data across hourly durations.

Duration (hours)	1	2	3	6	>6
Correction factor	1.08	1.04	1.03	1.01	1.00

Sub-hourly durations. No correction factors were applied to durations under 1-hour.

4.5.3. Inconsistencies across durations

At co-located stations it was not uncommon that extracted annual maxima differed during overlapping periods of record. 1-hour AMS at co-located hourly and 15-minute stations and 1-day AMS at co-located daily, hourly, and 15-minute stations were compared for overlapping periods of record. Each year with significantly different annual maxima at co-located stations was investigated. Effort was made to identify the source of the error and to correct erroneous observations across all durations that may be affected.

Annual maxima at each station were also compared across all durations in each year to ensure that extracted amount at a longer duration was at least equal to corresponding amount at the successive shorter duration. Inconsistencies of this type occurred primarily at stations with significant number of missing and/or accumulated data and resulted from different AMS extraction rules (Section 4.3) for different durations, or from the application of correction factors for constrained observations (Section 4.5.2). In those cases, shorter duration precipitation amounts were used to replace annual maxima extracted for the longer duration. Typically, adjustments of this type were very small.

4.5.4. Trend analysis

Precipitation frequency analysis methods used in NOAA Atlas 14 volumes are based on the assumption of a stationary climate over the period of observation (and application). Statistical tests for trends in AMS and the main findings for this project area are described in more detail in Appendix A.2. Briefly, the stationarity assumption was tested by applying a parametric *t*-test and non-parametric Mann-Kendal test for trends in the 1-day and 1-hour annual maximum series data at 5%

significance level. Only stations with at least 50 years of data were tested for trends. Outcomes from both tests were almost identical. Both tests indicated no statistically-significant trends in about 86% of hourly and 92% of daily stations. Tests detected positive trends in 14% of hourly and 5% of daily stations. No negative trends were detected in hourly data, and they were present in about 3% of daily AMS. Spatial maps did not reveal any large cohesive areas with either only positive or negative trends in AMS.

The relative magnitude of any trend in AMS was also assessed for the project area as a whole. AMS were rescaled by corresponding mean values and then regressed against time. The regression results were tested as a set against a null hypothesis of zero serial correlation. The null hypothesis of no trends in AMS data could not be rejected at 5% significance level.

Therefore, the assumption of stationary climate was accepted for this project area and no adjustment of AMS was recommended.

4.6. Precipitation frequency estimates with confidence limits at stations

4.6.1. Overview of methodology and related terminology

Precipitation magnitude-frequency relationships at individual stations have been computed using a regional frequency analysis approach based on L-moment statistics. Frequency analyses were carried out on annual maximum series (AMS) for the following nineteen durations: 5-minute, 10-minute, 15-minute, 30-minute, 1-hour, 2-hour, 3-hour, 6-hour, 12-hour, 1-day, 2-day, 3-day, 4-day, 7-day, 10-day, 20-day, 30-day, 45-day and 60-day. Frequency estimates based on partial duration series (PDS), which include all amounts for a specified duration at a given station above a pre-defined threshold regardless of year, were developed from AMS data using a formula that allows for conversion between AMS and PDS frequencies. To assess the uncertainty in estimates, 90% confidence intervals were constructed on AMS and PDS frequency curves.

Frequency analysis involves mathematically fitting an assumed distribution function to the data. The following distribution functions were analyzed in this project with the aim to identify a distribution that will provide accurate precipitation frequency estimates for the project area across all frequencies and durations: 3-parameter Generalized Extreme Value (GEV), Generalized Normal, Generalized Pareto, Generalized Logistic and Pearson Type III distributions; 4-parameter Kappa distribution; and 5-parameter Wakeby distribution.

When fitting a distribution to a precipitation annual maximum series extracted at a given location (and selected duration), the result is a frequency distribution relating precipitation magnitude to its annual exceedance probability (AEP). The inverse of the AEP is frequently referred to as the average recurrence interval (ARI), also known as return period. When used with the AMS-based frequency analysis, ARI does not represent the "true" average period between exceedances of a given precipitation magnitude, but the average period between years in which a given precipitation magnitude is exceeded at least once. Those two average periods can be considerably different for more frequent events. The 'true' average recurrence interval (ARI) between cases of a particular magnitude can be obtained through frequency analysis of PDS.

Differences in magnitudes of corresponding frequency estimates (i.e., quantiles) from the two series are negligible for ARIs greater than about 15 years, but notable at smaller ARIs (especially for ARI $\leq$ 5 years). Because the PDS can include more than one event in any particular year, the results from a PDS analysis are considered to be more reliable for designs based on frequent events (e.g., Laurenson, 1987). To avoid confusion, herein the term AEP is used with AMS frequency analysis and ARI with PDS frequency analysis. The term 'frequency' is interchangeably used to specify the ARI and AEP.

L-moments (Hosking and Wallis, 1997) provide an alternative way of describing frequency distributions to traditional product moments (conventional moments) or maximum likelihood approach. Since sample estimators of L-moments are linear combinations of ranked observations, they are less susceptible to the presence of outliers in the data than conventional moments and are well suited for the analysis of data that exhibit significant skewness. L-moments typically used to calculate parameters of various frequency distributions include 1st and 2nd order L-moments: L-location (λ_1) and L-scale (λ_2), and the following L-moment ratios: L-CV (τ), L-skewness (τ_3), and L-kurtosis (τ_4). L-CV, which stands for "coefficient of L-variation", is calculated as the ratio of L-scale to L-location (λ_2/λ_1). L-skewness and L-kurtosis represent ratios of the 3rd order (λ_3) and 4th order (λ_4) L-moments to the 2nd order (λ_2) L-moment, respectively, and thus are independent of scale.

One of the primary problems in precipitation frequency analysis is the need to provide estimates for average recurrence intervals that are significantly longer than available records. Regional approaches, which use data from stations that are expected to have similar frequency distributions has been shown to yield more accurate estimates of extreme quantiles than approaches that use only data from a single station. The number of stations used to define a region should be large enough to smooth variability in at-station estimates, but also small enough that regional estimates still adequately represent local conditions. The region of influence approach (Burn, 1990) used in this Volume defines regions such that each station has its own region with a potentially unique combination of nearby stations. Stations are selected based on the maximum allowable distance from the target station that is defined in a geographic space and in a space of selected statistical attribute variables. Like with other regionalization approaches, there is level of subjectivity involved in the process, for example, in choosing attribute variables, selecting the maximum allowable distances as well as attributes' weights and transformations for similarity distance algorithms. One of the main advantages, which is very relevant for the mapping of precipitation frequency estimates, of the region of influence approach is that it results in a smooth transition in estimates across regional boundaries.

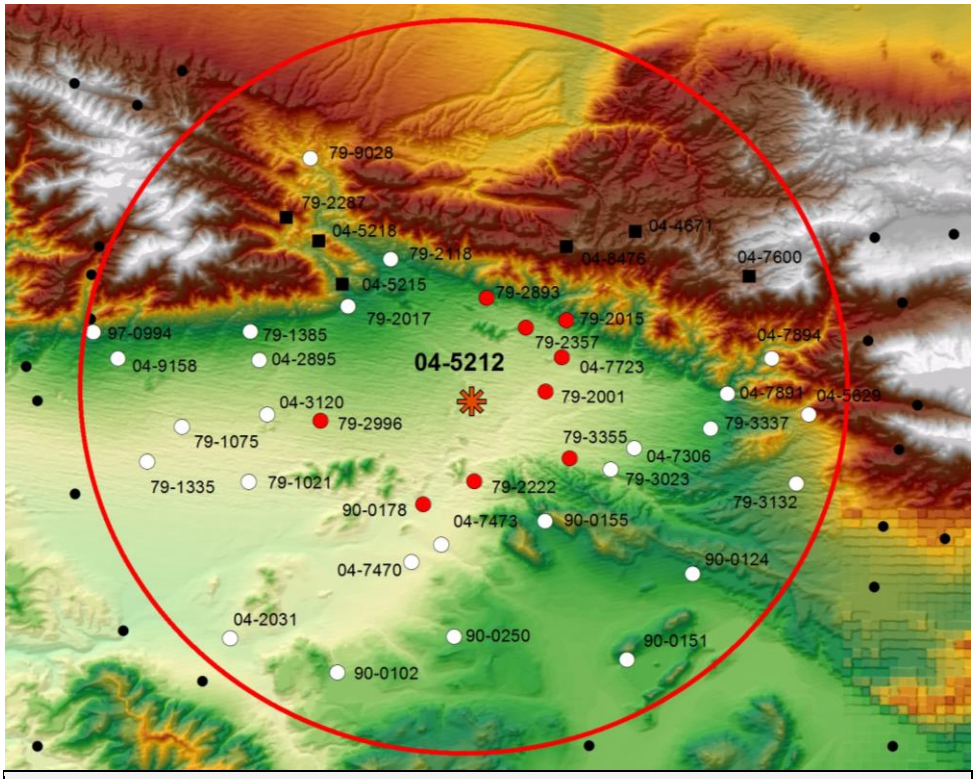
A frequency curve that is calculated from sample data represents some average estimate of the population frequency curve, but there is a high probability that the true value actually lies above or below the sample estimate. Confidence limits determine values between which one would expect the true value to lie with certain confidence. The width of a confidence interval between the upper and lower confidence limits is affected by a number of factors, such as the degree of confidence, sample size, exceedance probability, distribution selection, and so on. Simulation-based procedures were used in this project to estimate confidence limits of a 90% confidence interval on frequency curves.

Precipitation frequency estimates from this Atlas are point estimates, and are not directly applicable for an area. The conversion of a point to an areal estimate is usually done by applying an appropriate areal reduction factor to the average of the point estimates within the subject area. Areal reduction factors are generally a function of the size of an area and the duration of the precipitation. Since there are no areal reduction factors developed by NWS specifically for California, depth-area-duration curves from NOAA Atlas 2 (Miller et al., 1973), that are identical to curves from Technical Paper No. 29 (U.S. Weather Bureau, 1960) developed for the contiguous United States, or from Technical Memorandum HYDRO-40 (Zehr and Myers, 1984) developed for the semiarid Arizona and New Mexico, could be used for that purpose depending upon the climatology of the area of interest. The choice of the appropriate areal reduction factor to use in California is the responsibility of the user.

4.6.2. Regionalization

The region of influence method used in this project uses a maximum allowable distance calculated based on selected geographic and statistical attribute variables. Among stations that were (1) within a 20-mile radius from a target station, (2) at most 2,000 feet higher or lower than the target station, and

(3) had 1-day mean annual maximum precipitation amounts within ± 1.5 inches of the amount at the target station, the closest 10 stations were recommended for inclusion in the region. The 20-mile maximum distance rule was relaxed for areas with very few stations. Stations were then added to or removed from the regions based on further examination of their locations with respect to mountain ridges, etc. (see an example in Figure 4.6.1) and assessment of similarities/dissimilarities in the progression of relevant L-moment statistics across durations compared with other stations in the region (see Figure 4.6.2). Final numbers of stations per region varied, but except for a few isolated stations, it was typically between 8 and 10 with 400 or more cumulative number of data years.



Enter stations you want to add or remove from the 04-5212 region:_____

Station ID	Distance (mi)	Elev (ft)	Elev diff. (ft)	MAM (in)	MAM diff. (in)	n_{daily}	n_{hourly}
Suggested stations: diamond for target station; red circles for stations in its region							
04-5212	-	1160	-	2.36	-	61	61
79-2001	3.84	1047	-113	1.88	-0.48	51	51
79-2222	4.96	945	-215	1.72	-0.64	44	44
79-2357	5.33	1288	128	2.74	0.39	31	30
04-7723	5.37	1140	-20	2.39	0.04	105	30
79-3355	6.13	1193	33	1.70	-0.66	26	26

...							

Figure 4.6.1. An example of spatial plot with accompanying interactive table for station 04-5212, Lytle Creek Foothill Blvd., CA.

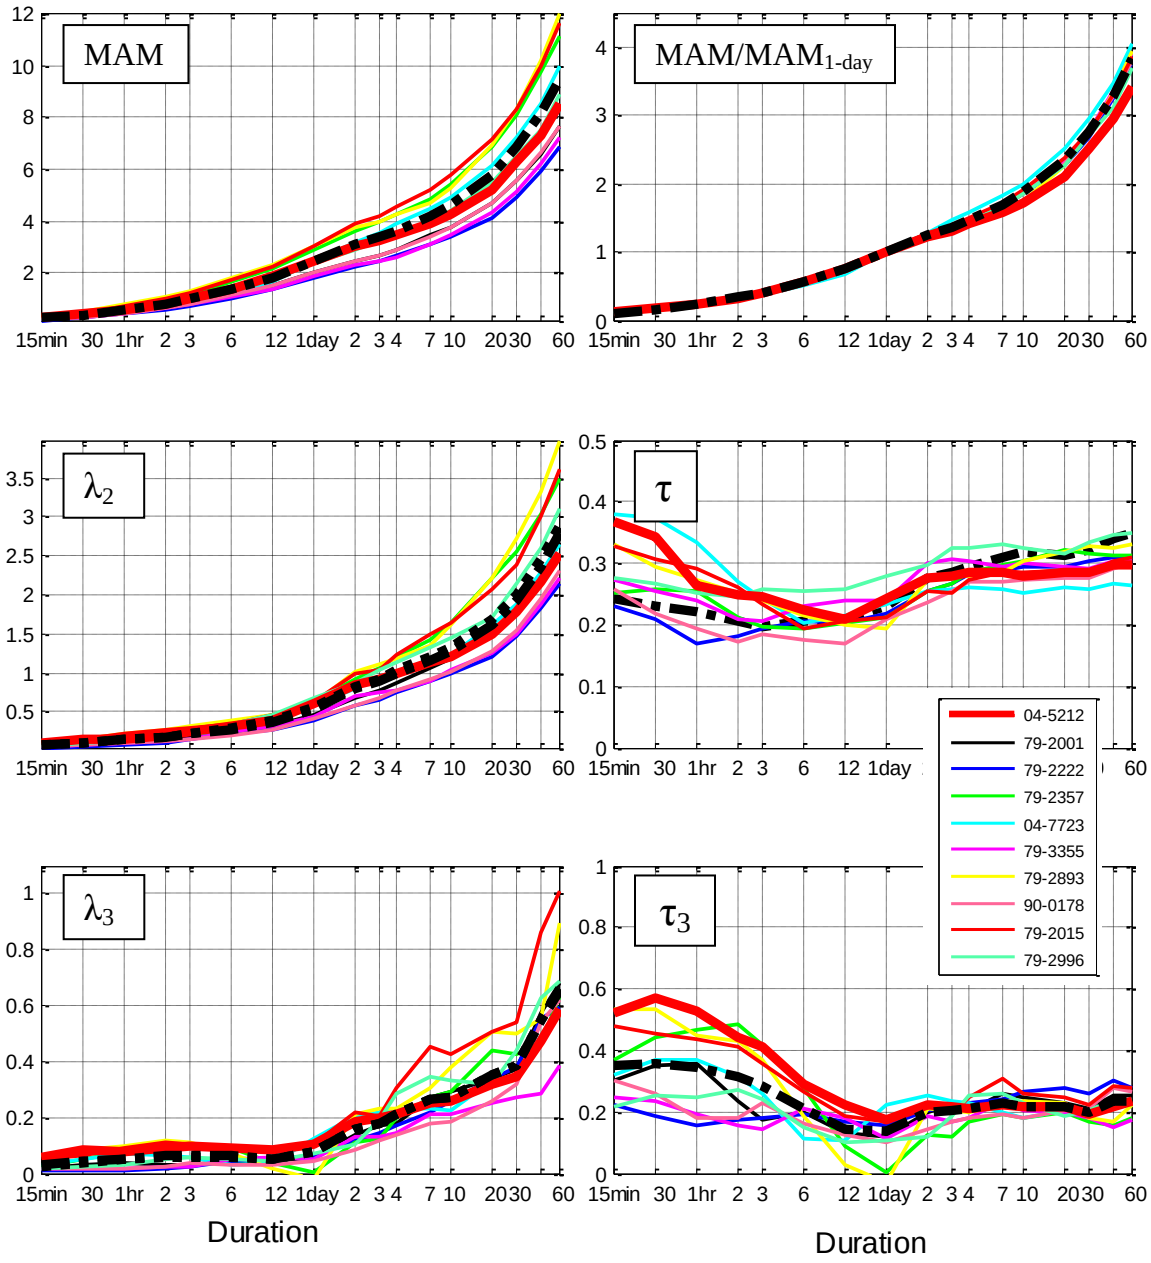

Figure 4.6.2. An example of plots of L-moments (left panels), MAM/MAM$_{1\text{-day}}$ and L-moment ratios (right panels) across durations for a region. Thick red lines show statistics for target station (station 04-5212); thin colored lines show statistics for other stations in the region; thick black lines show corresponding regional estimates.

Regional L-moments calculation. For a given duration, regional estimates of L-moment ratios (L-CV, L-skewness and L-kurtosis) were obtained by averaging corresponding station-specific estimates weighted by record lengths. Regional L-moment ratios were then used to estimate higher order L-moments at each station.

Station dependence. Since stations were selected based on geographic proximity to a target station, it was not uncommon that extracted annual maxima at nearby stations came from the same storm events. Dependence in AMS data for stations within a region was analyzed using a *t*-test at the 90% confidence level for correlation coefficients. Analysis indicated that cross-correlation among stations was statistically significant for a number of regions and that the number of dependent station pairs increased with duration length. Since the impact of station dependence on precipitation frequency estimates is minimal (e.g., Hosking and Wallis, 1997), it was not addressed in the calculation of precipitation frequency estimates. However, it was accounted for during the construction of confidence intervals on estimates where it could have noticeable influence (see Section 4.6.5).

4.6.3. AMS-based estimates

Choice of distribution. A goodness-of-fit test based on L-moment statistics for 3-parameter distributions, as suggested by Hosking and Wallis (1997), was used to assess which of the 3-parameter distributions listed in Section 4.6.1 provide acceptable fit to the AMS data. Based on this test, the GEV distribution, which is a distribution widely used in analysis of extreme events, was a suitable distribution for at least 80% of stations (regions) for each duration. The GEV distribution provided an acceptable fit to AMS data in more cases than any other 3-parameter distribution. Inspection of probability plots for 1-hour, 1-day and 10-day durations, like the one shown in Figure 4.6.3, also indicated that the GEV distribution estimates were often comparable to estimates from the 4-parameter Kappa or 5-parameter Wakeby distributions. Although it is not required to use the same type of distribution across all durations and/or regions, changes in distribution type for different durations or regions may lead to noticeable discontinuities in frequency estimates across durations or between nearby locations, particularly at rarer frequencies. The decision was made to adopt the GEV distribution across all stations and for all durations.

Frequency estimates for hourly and daily durations. For each station and for each duration, regional L-moment statistics were used to calculate the parameters of the GEV distribution and to produce precipitation frequency estimates for the following AEPs: 1/2, 1/5, 1/10, 1/25, 1/50, 1/100, 1/200, 1/500 and 1/1000. This calculation was repeated for all durations and for all stations.

Frequency estimates for sub-hourly durations. The shortest duration at which AMS data were extracted was 15 minutes. L-moments were calculated for the 15-minute and 30-minute durations at stations that had 15-minute AMS data available for at least one station assigned to their region. L-moments were then used to produce precipitation frequency estimates in the same manner as for hourly and daily durations. However, in a number of cases, it was observed that resulting precipitation frequency estimates were implausible, especially for AEPs of 1/100 (1%) or less. The primary cause of this was the sample size, as very few stations with measurements at sub-hourly durations were available, and when they were available, they typically had short periods of record. This resulted in unreliable moments (especially higher-order moments), and consequently, unreliable precipitation frequency estimates. λ_1 moments (i.e., mean annual maxima) were less sensitive to a sample size and were generally in line with corresponding estimates at nearby stations. λ_1 moments were also, for the most part, consistent with the expected progression across hourly and daily durations (see top left panel of Figure 4.6.2). For that reason, mean annual maxima at 15-minute and 30-minute durations were retained for derivation of MAM grids (see Section 4.8.1). At-station quantiles, which were assessed as unreliable, were not interpolated to create precipitation frequency grids; an alternative approach, described in Section 4.8.2 was used for that purpose.

5-minute and 10-minute estimates were calculated using scaling factors from the 15-minute estimates. The scaling factors were an average of all the ratios of 5-minute and 10-minute annual maxima and corresponding 15-minute annual maxima, respectively. To increase sample size when

developing the scaling factors, stations that reported observations at sub-hourly durations (so called n-minute stations) that were not adequate for frequency analysis, typically because their record lengths were too short, were also used; they are listed in Appendix A.1 (Table A.1.3). Average ratios per station did not show any spatially coherent clusters and did not vary much from station to station, so scaling factors were calculated by taking averages of all the ratios in the project area. The scaling factor for 5-minute duration was 0.58 and for 10-minute duration it was 0.82.

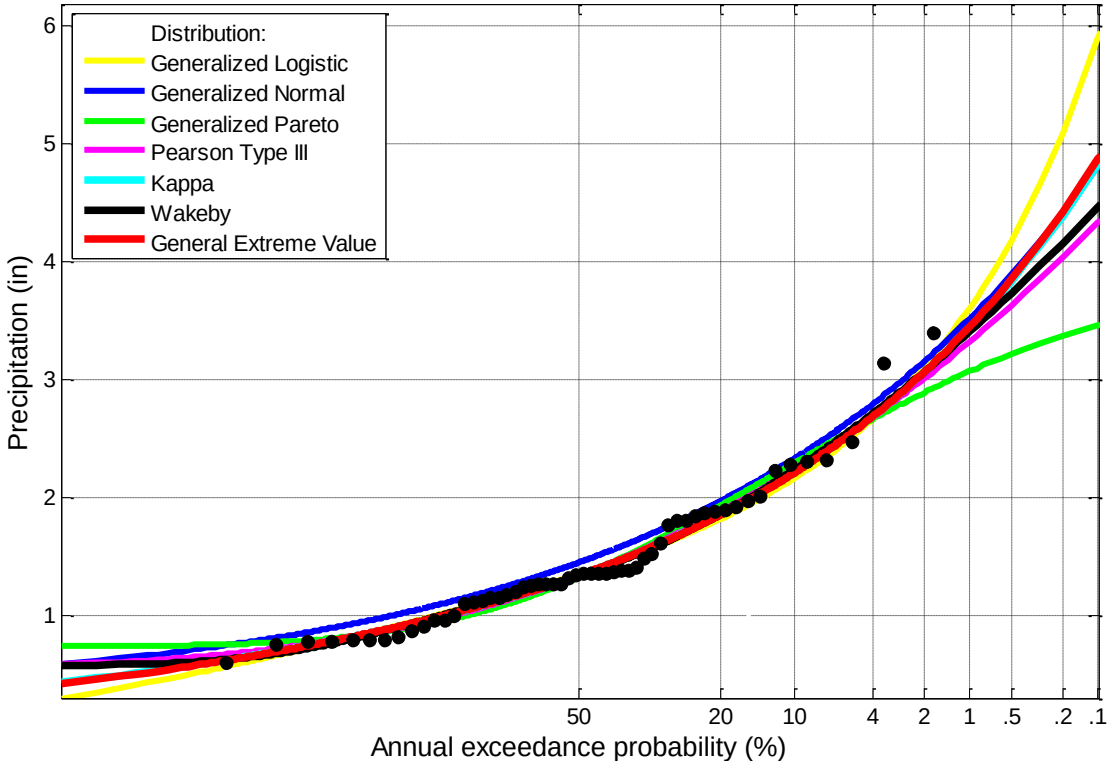

Figure 4.6.3. Probability plots for selected distributions for 1-day AMS at station 04-1476, Canby.

Consistency in frequency estimates across durations. Since regional L-moments, and consequently, precipitation frequency estimates, were calculated independently for each duration, transitions in estimates across durations were not always smooth. At a few stations it was observed that for a given AEP, the quantile for a shorter duration was higher than the quantile at the next longer duration. This anomaly typically occurred at AEPs of 1/100 or less. In the majority of anomalous cases, sampling variability caused L-moments (especially λ_3) to wander more widely from the expected development across durations. Also, in transition from 12-hours to 24-hours, record lengths often changed since fewer hourly data were available compared to daily. When L-moments were smoothed across durations, depth-duration-frequency (DDF) curve patterns improved. Figure 4.6.4 illustrates precipitation depth-duration-frequency curves before and after smoothing L-moments for station 97-1199, Griffith Park Nursery, CA. Appendix A.3 lists the smoothed L-moments used to compute precipitation frequency estimates at each station for 1-hour through 60-day durations.

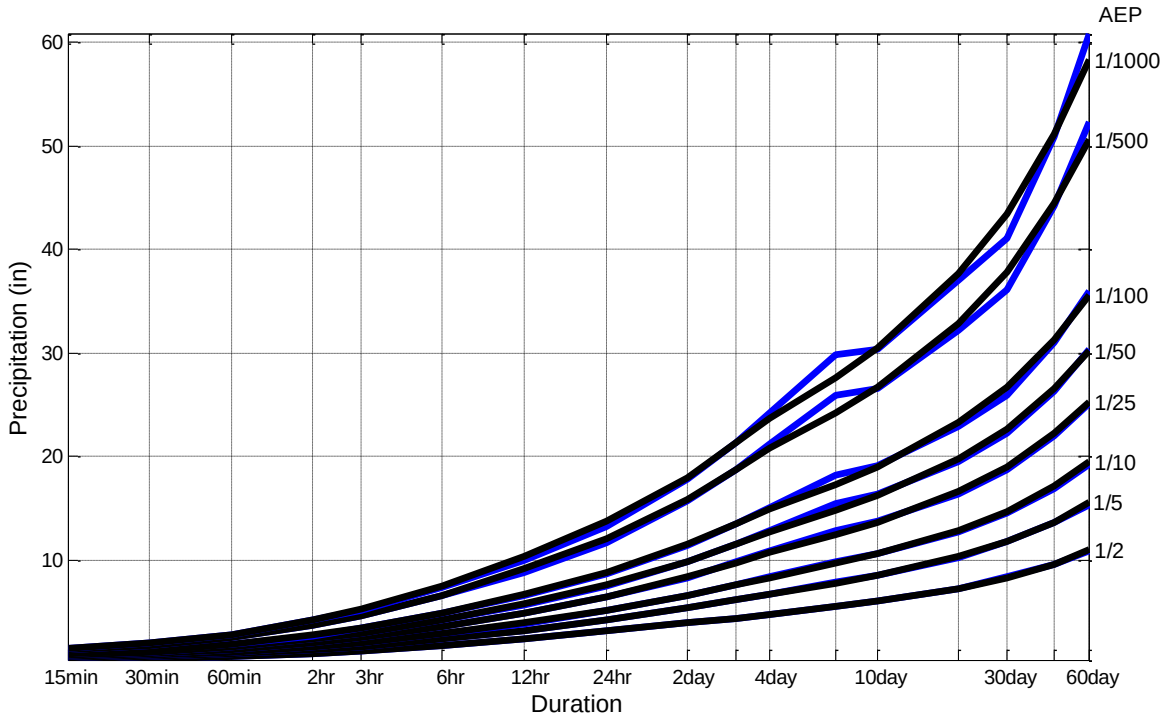

Figure 4.6.4. Precipitation frequency estimates for a range of durations for selected AEPs for station 97-1199. Blue lines represent original estimates; black lines represent estimates obtained after L-moments were smoothed across durations.

4.6.4. PDS-based estimates

PDS-based precipitation frequency estimates were calculated indirectly from the Langbein's formula (Langbein, 1949) that transforms a PDS-based average recurrence interval (ARI) to an annual exceedance probability (AEP):

$$\mathrm{AEP} = 1 - \exp\left(-\frac{1}{\mathrm{ARI}}\right).$$

PDS-based frequency estimates were calculated for the same durations as AMS-based estimates for 1-, 2-, 5-, 10-, 25-, 50-, 100-, 200-, 500- and 1,000-year ARIs. Selected ARIs were first converted to AEPs using the above formula and then used to calculate precipitation frequency estimates following the same regional approach and using the same L-moments that were used in the AMS analysis. For sub-hourly durations for which data were not available, PDS-based based frequency estimates were calculated using the same scaling factors that were used to estimate AMS-based frequency estimates.

4.6.5. Confidence limits

A Monte Carlo simulation procedure, as described in Hosking and Wallis (1997), was used to construct 90% confidence intervals (i.e., 5% and 95% confidence limits) on both AMS-based and PDS-based precipitation frequency curves. Since the station dependence analysis (Section 4.6.2) indicated that AMS data from different stations in a region were frequently highly correlated (especially for longer durations), the algorithm was adjusted to account for inter-station correlation. At each station, 1,000 simulated data sets per duration were used to generate precipitation quantiles. At a given frequency, estimates were sorted from smallest to largest and the 50^{th} value was selected as the lower confidence limit and the 950^{th} value was selected as the upper confidence limit.

Confidence limits for sub-hourly durations for which data were not available were calculated using the same scaling factors that were used to calculate frequency estimates. Since confidence limits were derived for each duration independently, they were smoothed across durations to reduce the effect of sampling variability using similar procedures as for the precipitation frequency estimates.

4.7. Rainfall frequency estimates with confidence limits at stations

4.7.1. Background

Precipitation frequency estimates from Section 4.6 represent precipitation magnitudes regardless of the type of precipitation. For some applications it may be important to differentiate frequency estimates from liquid precipitation (i.e., rainfall) only. For example, rainfall is treated differently from snowfall in watershed modeling because of different runoff producing mechanisms: while the rainfall generates runoff almost immediately, snowfall generally goes into storage until it melts and produces runoff at a later date.

For high elevation areas in California, the contribution of snowfall to the total yearly precipitation amount is significant. However, that does not necessarily directly translate to its significant participation in precipitation annual maximum series (AMS). To explore differences in total and liquid-only precipitation frequency estimates, concurrent rainfall and precipitation AMS were extracted at stations which had information useful for distinguishing the type of precipitation. Rainfall frequency analysis was done for durations up to 24 hours, which are of most interest to design projects relying on peak flows.

4.7.2. Estimates with confidence limits

Estimates for 24-hour duration. Concurrent daily precipitation and snowfall measurements were available from the NCDC's DSI-3200 dataset. 318 stations with at least 40 years of both precipitation and snowfall data were used in this analysis. The number of stations per various elevation ranges is given in Table 4.7.1. Station locations are shown in Figure 4.7.1.

Table 4.7.1. Number of stations used for 24-hour rainfall frequency analysis grouped by elevation.

Elevation (ft)	Number of stations
< 3000	216
3000 - 4000	27
4000 - 5000	48
5000 - 6000	13
6000 - 8000	8
8000 - 10000	6

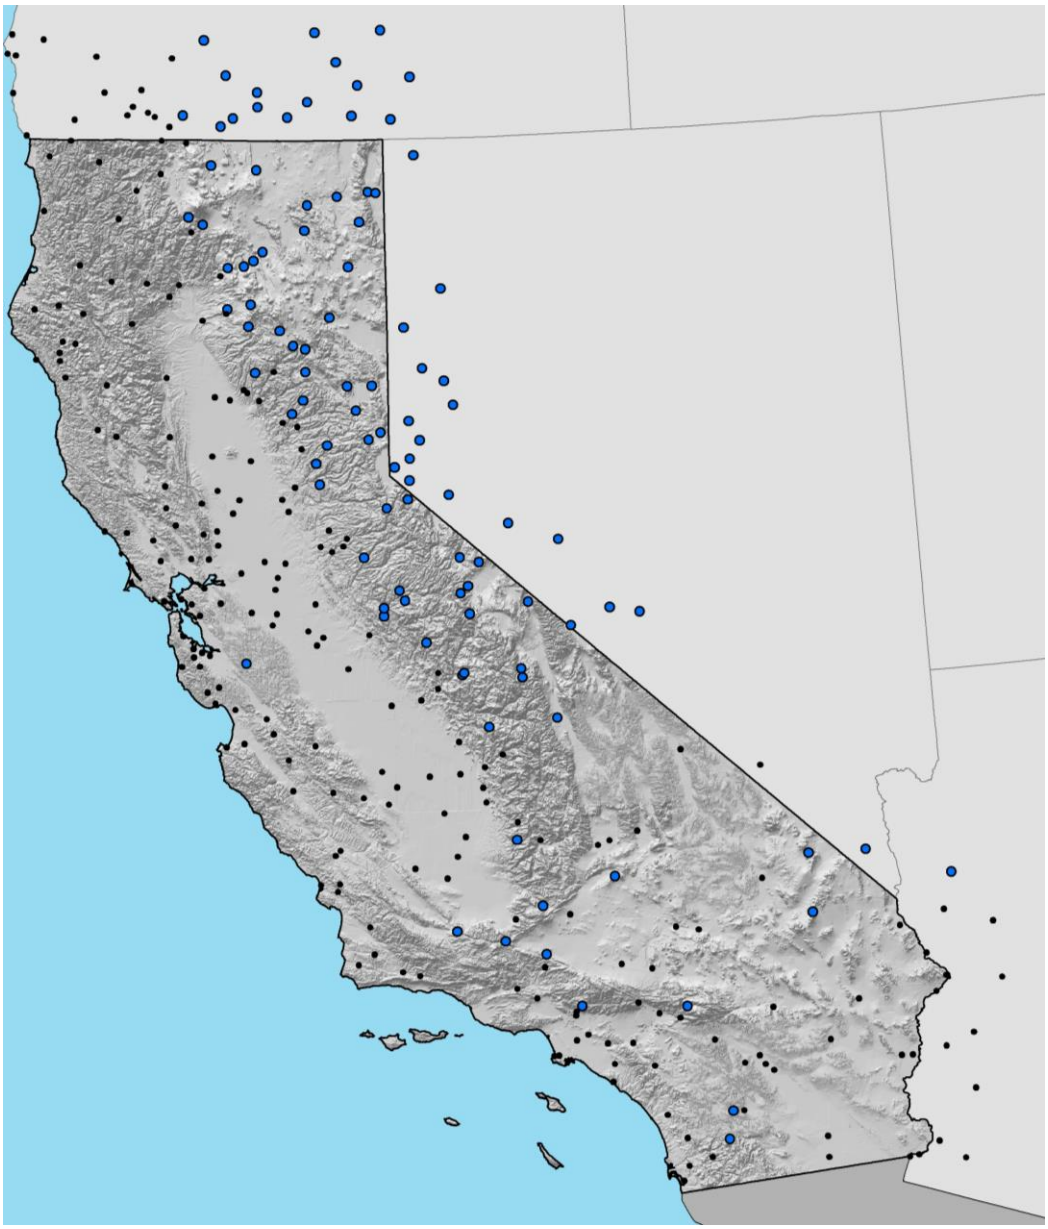

Figure 4.7.1. Map of stations recording both precipitation and snowfall at 1-day interval used for rainfall frequency analysis. Blue dots indicate stations above 3,000 feet and black dots indicate stations below 3,000 feet.

Recorded snowfall amounts were first converted to snow water equivalent using the 10 to 1 rule, which assumes that the density of water is 10 times the density of snowfall. Rainfall amounts were then calculated as a difference between precipitation and snow water equivalent. Frequency analysis was done on at-station rainfall-only AMS and on total precipitation AMS using the Generalized Extreme Value (GEV) distribution with parameters estimated from L-moment statistics. For stations below 3,000 feet, there was very little difference between precipitation and rainfall frequency estimates. As expected, as elevation increased, more snowfall events were observed in the precipitation AMS, but still, snowfall only occasionally ranked among the highest values in the series (see example in Figure 4.7.2). Various types of regression equations were investigated to relate

rainfall frequency estimates with precipitation frequency estimates, elevations and frequencies (AEP or ARI) for stations above 3,000 feet. Precipitation frequency estimates, which were highly correlated among themselves across frequencies (see Section 4.8.2), were also highly correlated with elevation, so elevation was not kept in regression equations. Correlation coefficients were a bit higher when a separate equation was developed for each frequency, and the relationship did not improve much using non-linear equations. The final set of equations, one for each frequency, is in the form: $Rainfall_{frequency,\ duration} = a + b\ Precipitation_{frequency,\ duration}$.

Coefficients *a* and *b* for all equations are shown in Table 4.7.2.; correlation coefficients were all between 0.89 and 0.98.

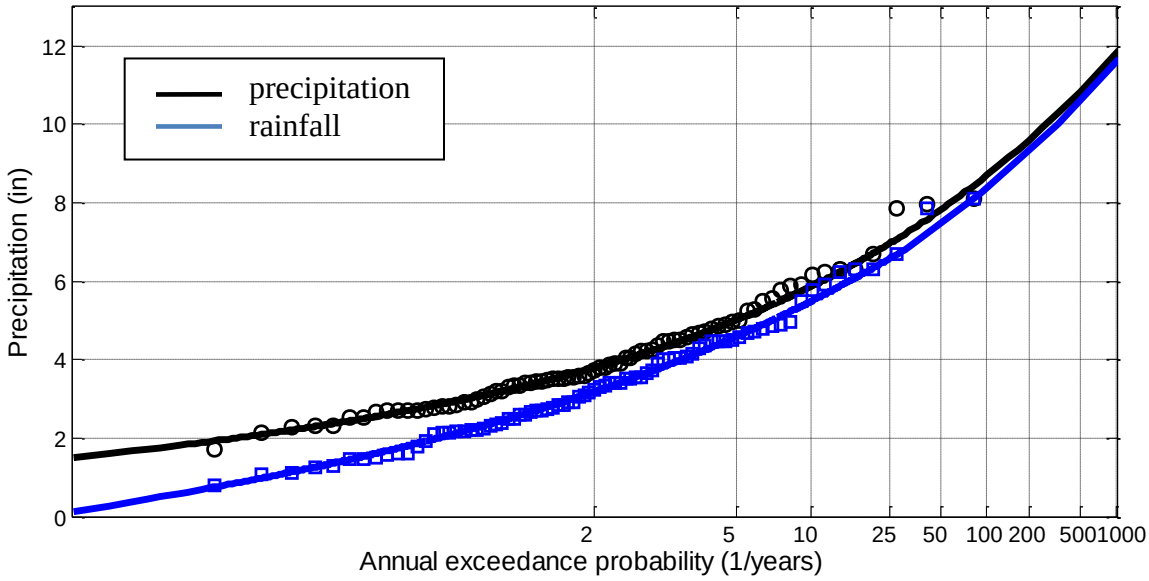

Figure 4.7.2. Probability distributions for the 24-hour precipitation and rainfall annual maximum series at station 04-1277, Calaveras Big Trees, CA (elevation 4,695 ft).

Table 4.7.2. Coefficients for equations relating 24-hour rainfall and precipitation frequency estimates for locations above 3,000 feet.

AEP	ARI (years)	*a* (in)	*b*
-	1	0.064	0.765
1/2	-	0.065	0.771
-	2	0.066	0.778
1/5	-	0.070	0.811
-	5	0.071	0.818
1/10	10	0.081	0.848
1/25	25	0.096	0.873
1/50	50	0.121	0.892
1/100	100	0.173	0.905
1/200	200	0.175	0.920
1/500	500	0.187	0.950
1/1000	1000	0.195	0.965

Since coefficients *a* (intercept values) were negligible relative to the magnitudes of corresponding precipitation frequency estimates, the results can be interpreted in terms of ratios of corresponding rainfall and precipitation frequency estimates. For example, 2-year rainfall frequency estimates are 23% lower than corresponding precipitation frequency estimates for locations above 3,000 feet. The ratios approach 100% for longer ARIs. The results are consistent with findings that most of the highest amounts in the precipitation AMS (which have the most effect on frequency estimates for very long ARIs) are from rainfall events.

Estimates for sub-daily durations. While daily snowfall measurements were readily available from NCDC's dataset, there were a very limited number of hourly stations with any information on type of precipitation, especially with longer periods of record to allow for meaningful statistical analysis of rainfall-only data. Temperature measurements at hourly time steps which could be used to distinguish liquid from solid precipitation were also available for only a limited number of locations, and typically for less than 10 years. Modeled hourly temperature profile data from the North American Regional Reanalysis (NARR) 3-hour gridded dataset (Mesinger et al., 2006; data available from http://www.emc.ncep.noaa.gov/mmb/rreanl/), were insufficient to distinguish between liquid and solid precipitation since ultimately subjective decisions were required in many cases analyzed. In the end, daily maximum and minimum temperature measurements from co-located daily stations were used to classify precipitation amounts as solid or liquid. 96 stations that had at least 30 years of both hourly precipitation and daily temperature data, 37 of which were above 3,000 feet, were used in this analysis. The number of stations per various elevation ranges is given in Table 4.7.3. Station locations are shown in Figure 4.7.3.

Table 4.7.3. Same as Table 4.7.2 but for hourly durations.

Elevation (ft)	Number of stations
< 3000	68
3000 - 4000	10
4000 - 5000	9
5000 - 6000	5
6000 - 8000	4
8000 - 10000	0

Hourly precipitation measurements were categorized as rainfall based on the time of day and the maximum, minimum, or average daily temperature. Measurements were classified as rainfall if taken between 9 pm and 9 am local time and the minimum daily temperature was above 32º F, or if taken between 12 pm and 6 pm and the maximum daily temperature was above 32º F, or if taken at any other time of day and the average daily temperature, calculated as the mean of maximum and minimum temperatures, was above 32º F. Precipitation and rainfall-only AMS were extracted from 1-hour data for selected hourly durations (1-, 2-, 3-, 6-, and 12-hour).

Similar to analysis done for 24-hours, frequency analysis was done on rainfall-only AMS and on total precipitation AMS using the GEV distribution with parameters estimated from L-moment statistics. Using the data from stations above 3,000 feet, regression equations were developed between rainfall frequency estimates and precipitation frequency estimates for different frequencies for each duration. Coefficients *a* and *b* for the equations are shown in Table 4.7.4. A few slope coefficients were slightly adjusted to avoid inconsistencies in estimates across frequencies. As can be seen from the table, differences between rainfall and precipitation frequency estimates are much

smaller than for 24-hour duration, and are almost negligible for shorter durations. Therefore, no adjustment was needed for sub-hourly durations.

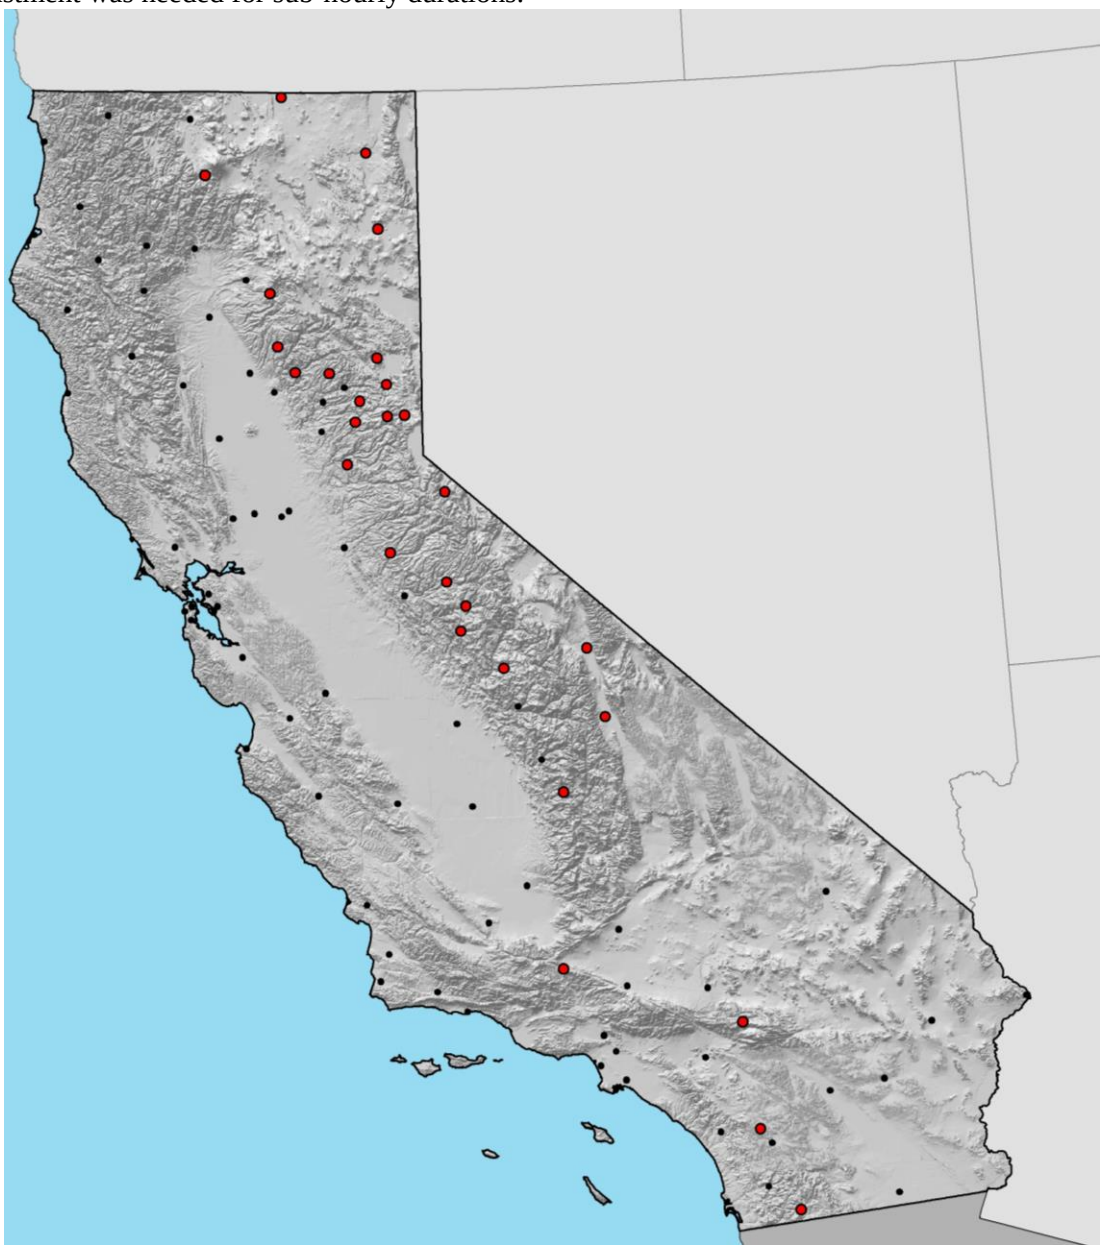

Figure 4.7.3. Map of hourly stations used for rainfall-only frequency analysis. Red dots indicate stations above 3,000 feet and black dots indicate stations below 3,000 feet.

Confidence limits. The same equations developed for rainfall frequency estimates were used to estimate confidence limits for AMS-based and PDS-based rainfall frequency estimates from their corresponding upper and lower limits of precipitation frequency estimates.

4.8. Derivation of grids

4.8.1. Mean annual maximum precipitation

Mean annual maximum (MAM) grids served as the basis for deriving gridded precipitation frequency estimates at different frequencies and durations. The station mean annual maximum values for the 17 selected durations between 15 minutes and 60 days were spatially interpolated to produce corresponding mean annual maximum grids at 30 arc-seconds (about 800 x 800 meters or 2,642 by 2,642 feet) resolution using a hybrid statistical-geographic approach for mapping climate data named Parameter-elevation Regressions on Independent Slopes Model (PRISM) developed by Oregon State University's PRISM Climate Group (e.g., Daly et al., 2002).

Intermediate review of mean annual maxima grids suggested that in a few areas of varied terrain, where the lack of stations unduly influenced expected spatial patterns, it was beneficial to add mean annual maximum estimates for selected locations to anchor the spatial interpolation. MAMs were estimated for one or more durations at nine locations shown in Table 4.8.1.

Table 4.8.1. Locations where mean annual maxima were estimated to anchor spatial interpolation.

Location ID	Location name	Latitude	Longitude	Elevation (ft)
00-0001	Old Man Mtn	34.5039	-119.4419	4370
00-0002	Bonny Doon Airport	37.0769	-122.1343	2200
00-0003	Mount Diller	40.4642	-121.5461	9000
00-0004	King Peak	40.1569	-124.1242	4050
00-0005	Big Pine Mtn	34.6974	-119.654	6850
00-0006	Cabezo Prieto Peak	36.283	-121.7747	3544
00-0007	Mount Harvard	34.2133	-118.0622	5436
00-0008	San Gorgonio Wilderness	34.1006	-116.8286	14,766
00-0009	Sequia National Park	36.6187	-118.6682	10,665

Appendix A.4 provides detailed information on the PRISM-based methodology for creating mean annual maximum grids. In summary, a unique regression function was developed for each target grid cell to derive mean annual maximum values for each duration that accounted for the difference between an observing station and the target cell's mean annual precipitation, topographic facet,

coastal proximity, the distance of an observing station to the target cell, etc. Because of the limited number of stations recording at durations shorter than 1 day, sub-daily mean annual maximum data were developed for daily-only stations when modeling mean annual maxima for 15-minute through 12-hour durations (see Appendix A.4 for more detail).

Jacknife cross-validation indicated that, for this project area, overall bias was less than 2.5 percent and the mean absolute error was less than 10.5 percent across all durations.

4.8.2. Precipitation frequency estimates with confidence limits

Estimates for 60-minute through 60-day durations. An HDSC-developed spatial interpolation technique termed the Cascade, Residual Add-Back (CRAB) was used to convert mean annual maximum grids into grids of AMS-based and PDS-based precipitation frequency estimates for durations from 60-minutes through 60-days. The procedure is based on the approach developed by the National Climatic Data Center used to derive several maps in the Climate Atlas of the United States (Plantico et al., 2000).

The technique derives grids along the frequency dimension with station precipitation frequency estimates for different durations being separately interpolated. Hence, the evolution of frequency-dependent spatial patterns for a given duration is independent of other durations. The CRAB process utilizes the inherently strong linear relationship that exists between mean annual maxima and precipitation frequency estimates for the 2–year average recurrence interval (ARI), as well as between precipitation frequency estimates for consecutive ARIs. Figure 4.8.1 shows an example of the relationship for the 24-hour duration between the 50-year and 100-year estimates for California. The R^2 value here of 0.99 is very close to 1.0, which was common for all relationships. Since this equation was calculated using all stations in the project area, the slope coefficient of 1.132 can be thought of as an average domain-wide ratio between 100-year and 50-year quantiles for 24-hour duration.

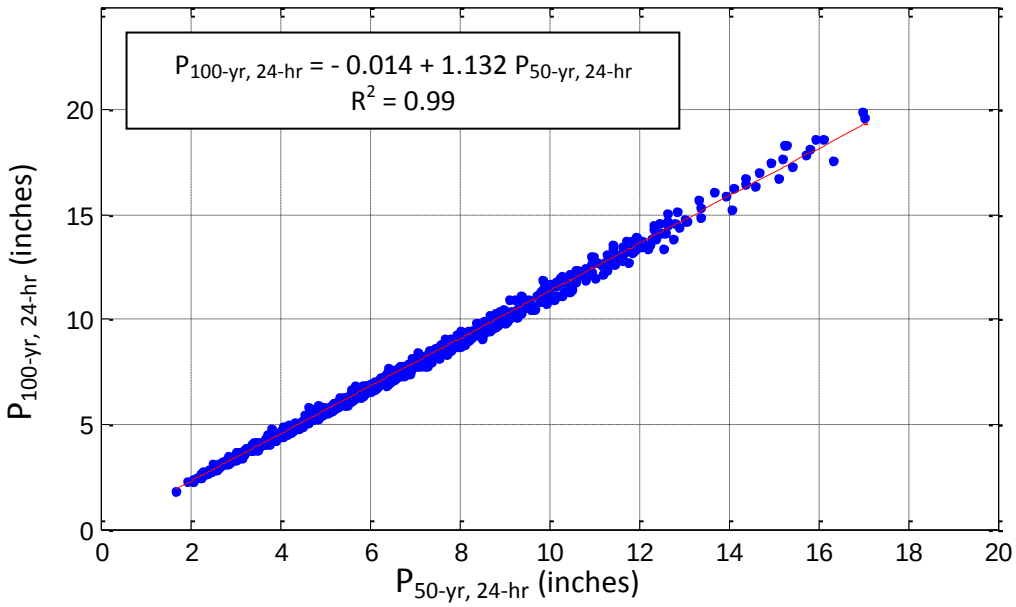

Figure 4.8.1. Scatter plot of 100-year versus 50-year precipitation frequency estimates based on 24-hour annual maximum series. Linear regression line is also shown.

For each duration, the cascade began with the PRISM-derived mean annual maximum (MAM) grid as the initial predictor grid and the 2-year precipitation frequency estimates as the subsequent grid. For a given duration, a single linear regression relationship was developed for mean annual maxima (predictor) and 2-year precipitation frequency estimates (predictant) from all stations in the project area. As a result of spatial smoothing during PRISM interpolation, it was possible that at-station MAM values calculated directly from AMS data were slightly different than corresponding PRISM-derived grid cell MAM estimates. To account for that difference, the PRISM MAMs were extracted for each station location and used in the computation of precipitation frequency estimates. The global linear regression relationship was applied to the MAM grid to establish the initial grid for 2-year estimates.

Residuals were then computed for each station to quantify the difference between at-station estimates and initial gridded estimates. The residuals were normalized by the mean annual maxima and spatially interpolated to a grid using an inverse-distance-weighting (IDW) algorithm. The IDW method used in CRAB estimated the values at ungauged locations based on information from the nine closest stations. Weights were inversely proportional to the power of the distance in miles. The IDW interpolation method was selected because by definition it is an exact interpolator and therefore remains faithful to the normalized residuals at stations. Also, normalized residuals were highly correlated, so a distance-weighting type of interpolation method was appropriate. The normalized residual grid was then multiplied by the original spatially interpolated mean annual maximum grid to obtain a spatially interpolated grid of actual residuals for the entire project area. The spatially interpolated grid of actual residuals was added back to the initial grid of 2-year estimates to create a grid of 2-year precipitation frequency estimates.

In the subsequent run, 2-year precipitation frequency estimates from all stations in the project area became the predictor grid and 5-year estimates became the variable to be predicted, and so forth. 2-year precipitation frequency estimates also served as predictors for 1-year estimates.

To ensure consistency in grid cell values across all durations and frequencies, duration-based and frequency-based internal consistency checks were conducted. Frequency-based internal consistency violations (e.g., 100-year estimate < 50-year estimate) were rare and negligible relative to the precipitation frequency estimates involved. Duration-based internal consistency violations (e.g., 24-hour estimate < 12-hour estimate) were more common, but again violations were small relative to the magnitude of precipitation frequency estimates. For inconsistent cases, the longer duration or rarer frequency grid cell value was adjusted by multiplying the shorter duration or lower frequency grid cell value by 1.01 to provide a 1% difference between the values. One percent was chosen over a fixed factor to allow the difference to change according to the grid cell magnitudes while at the same time providing a minimal, but sufficient, adjustment without changing otherwise compliant data in the process. Grid cell consistency was ensured first across durations and then across frequencies.

Jack-knife cross-validation technique (Shao and Tu, 1995) was used to evaluate CRAB performance for interpolating precipitation frequency estimates. It was cost prohibitive to re-create the PRISM mean annual maximum grids for each cross-validation iteration. For this reason, the cross-validation results reflect the accuracy of the CRAB procedure based on the same mean annual maximum grids. Figure 4.8.2 shows validation results for 100-year, 60-minute estimates as a histogram representing the distribution of differences in 100-year 60-minute estimates with and without each station. For more than 90% of stations in the project area, differences were less than ±2%. The largest differences were up ±10%, but they occurred in less than 1% of all stations. Based on the results shown in the figure, overall, CRAB adequately reproduced values in the absence of station data.

Estimates for sub-hourly durations. Because of the small number of data available for durations shorter than 1-hour, precipitation frequency grids for those durations were developed differently.

Although PRISM MAM grids were available for 30-minute and 15-minute durations, the spatial patterns of precipitation frequency estimates developed though CRAB were considered less reliable. Therefore, the precipitation frequency grids for the 30-minute duration were derived by creating a grid of ratios between 30-minute MAM and 60-minute MAM grids. This ratio grid was then multiplied by the 60-minute precipitation frequency grids for all average recurrence intervals. 15-minute precipitation frequency grids were developed in a similar fashion. The 15-minute precipitation frequency grids were then multiplied by scaling factors of 0.82 and 0.58 (Section 4.6.3) to develop precipitation frequency grids for the 10-minute and 5-minute durations, respectively.

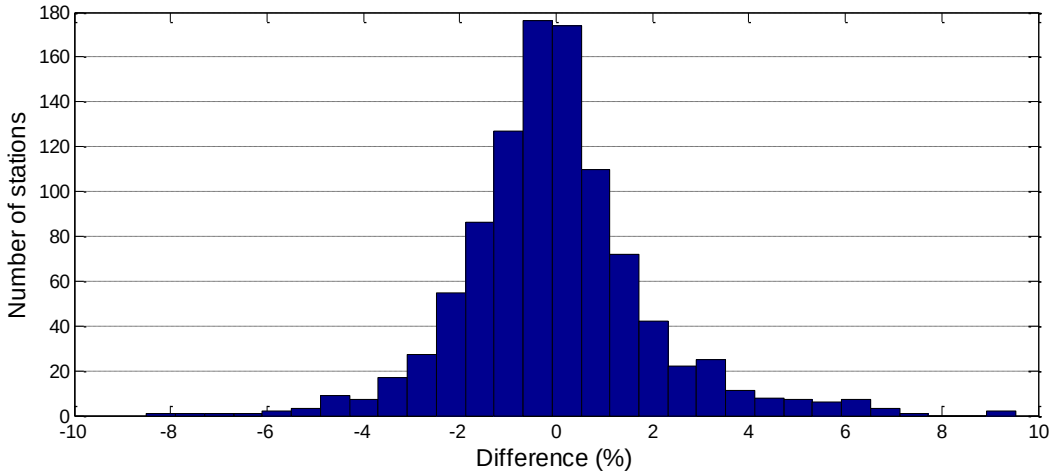

Figure 4.8.2. NOAA Atlas 14 Volume 6 jackknife cross-validation results for 100-year 60-minute estimates.

Confidence limits. For the 60-minute through 60-day durations, grids of upper and lower limits of the 90% confidence interval for the precipitation frequency estimates were also derived using the CRAB procedure. Similar to the precipitation frequency estimates, upper and lower limits exhibited strong linear relationships at consecutive average recurrence intervals. The PRISM-produced mean annual maximum grid for a given duration was used as the predictor for the 2-year upper (lower) limit grids. The global linear regression relationship was applied to the MAM grid to establish the initial grid for 2-year upper (lower) limit estimates. At-station residuals were spatially interpolated and used to develop the upper (lower) limit grids. In the subsequent run, 2-year upper (lower) limit estimates from all stations in the project area become predictor for 5-year upper (lower) limit estimates, and so forth. Like the precipitation frequency grids, frequency-based and duration-based adjustments were made when needed for consistency.

For sub-hourly durations, upper and lower limit grids were derived in the same manner as precipitation frequency grids. Estimates for all average recurrence intervals for the 30-minute and 15-minute limits were derived by multiplying 60-minute upper (lower) limit grids with a grid of the ratios between the 30-minute or 15-minute MAM grids, respectively, and 60-minute MAM grids. Grids for upper (lower) limits for 10-minute and 5-minute durations were then developed by multiplying 15-minute upper (lower) grids by scaling factors of 0.82 and 0.58, respectively.

4.8.3. Rainfall frequency estimates with confidence limits

The regression equations described in Section 4.7 were applied to final grids of precipitation frequency estimates and upper and lower confidence limits to develop corresponding grids for rainfall. The grids were created for 1-, 2-, 3-, 6-, 12- and 24-hour durations.

5. Precipitation Frequency Data Server

5.1. Introduction

NOAA Atlas 14 precipitation frequency estimates are delivered entirely in digital form in order to make the estimates more widely available and to provide them in various formats. The Precipitation Frequency Data Server (PFDS; http://hdsc.nws.noaa.gov/hdsc/pfds/) is a point-and-click interface developed as the primary web portal for precipitation frequency estimates and associated information.

5.2. Underlying data

The PFDS operates from a set of ASCII grids of precipitation frequency estimates and lower and upper bounds of the 90% confidence interval. The grids can be downloaded from the website and imported into a Geographical Information System (GIS). Table 5.2.1 shows the complete set of ARIs and durations for which PDS-based frequency estimates are available from the PFDS for any location in the project area. Similarly, Table 5.2.2 shows the complete set of annual exceedance probabilities and durations for which AMS-based frequency estimates with confidence limits are available from the PFDS for any particular location. AMS-based and PDS-based rainfall frequency estimates are available for the same set of frequencies for durations from 1-hour to 24-hour.

The ASCII grids, which represent the official estimates, have the following pertinent metadata:

- Resolution: 30-arc seconds (about 800 x 800 meters or 2642 x 2642 feet);
- Units: inches*1000 (integer);
- Projection: geographic (longitude/latitude);
- Datum: NAD 83.

Table 5.2.1. Average recurrence intervals and durations for which PDS-based precipitation frequency estimates with 90% confidence intervals are available from the PFDS.

Duration	Average recurrence interval (ARI)									
	1-yr	2-yr	5-yr	10-yr	25-yr	50-yr	100-yr	200-yr	500-yr	1,000-yr

5.3. Products available on the Precipitation Frequency Data Server

The PFDS homepage (http://hdsc.nws.noaa.gov/hdsc/pfds/) has a clickable map of the United States. Upon clicking on California or selecting the state name from the drop-down menu, an interactive map of California and its surrounding area is displayed (see Figure 5.3.1). A location for which precipitation frequency estimates are needed can be selected by:

- Manually entering latitude and longitude coordinates in decimal degrees (negative numbers should be entered for southern hemisphere latitudes and for western hemisphere longitudes);
- Selecting a station from a pull-down list;
- Dragging the red cursor to a location on the map;
- Clicking on an observing station on the map (after selecting "show stations on map" and zooming in).

From the menu at the top of the page, a user can select PDS-based or AMS-based precipitation frequency estimates, units and whether estimates should be displayed as precipitation depths or intensities.

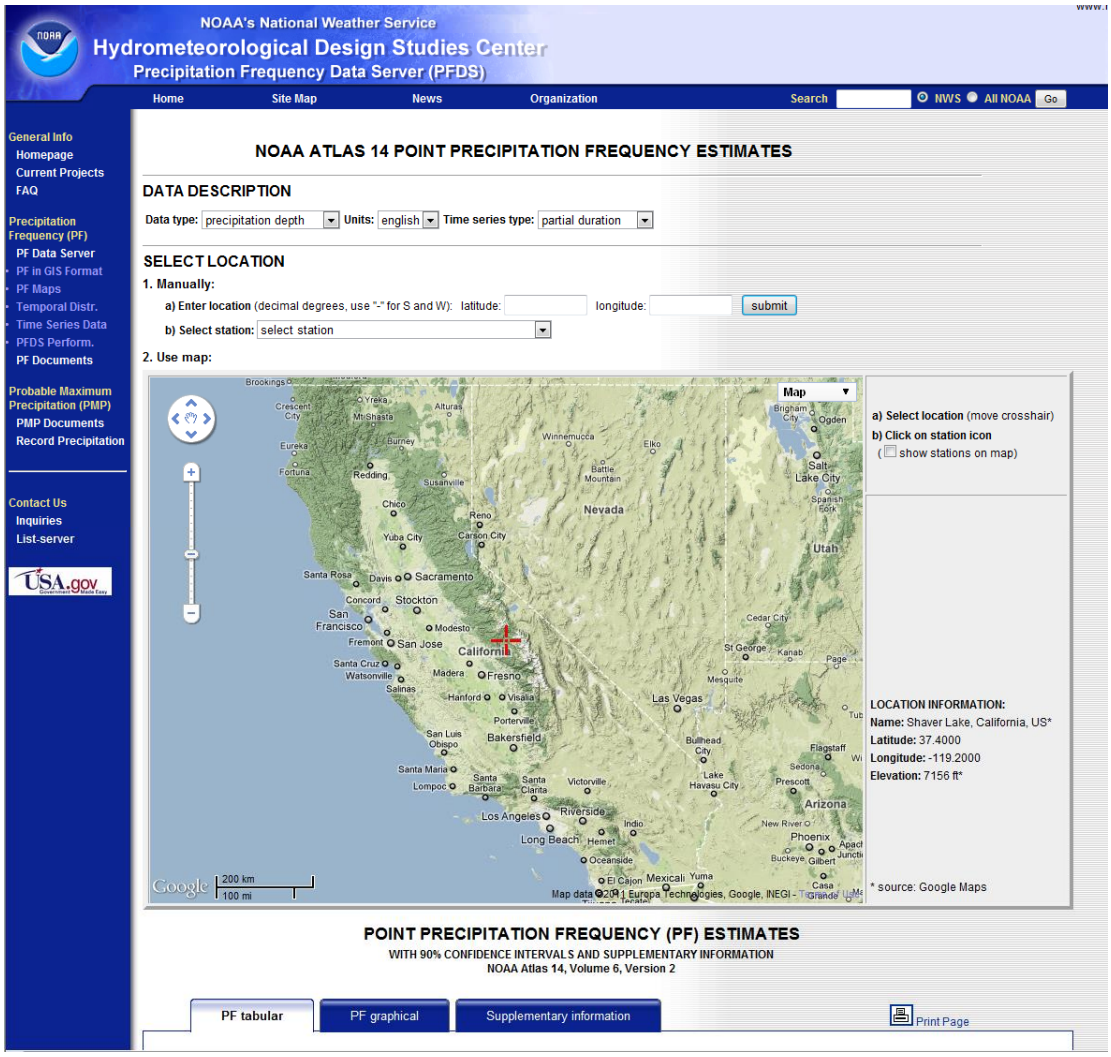

Figure 5.3.1. Initial view of the interactive map of California.

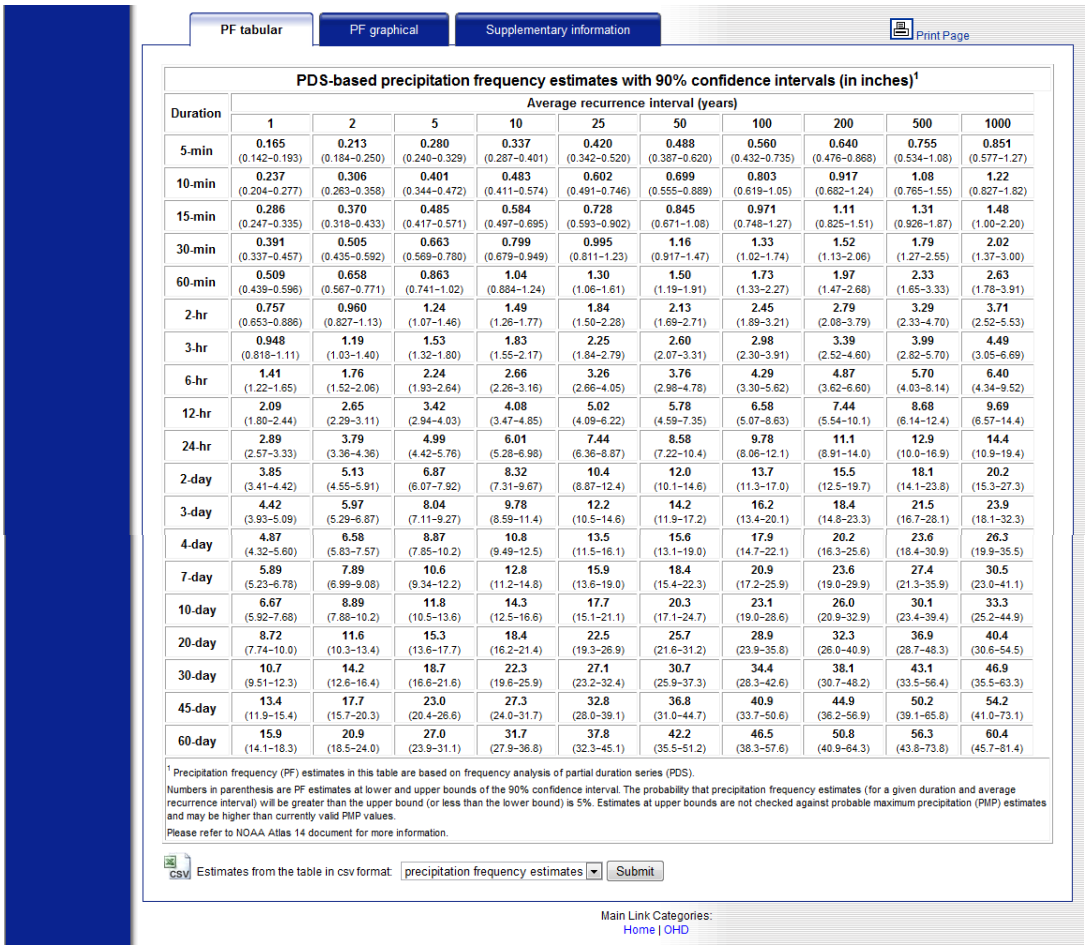
After a location is selected, all precipitation frequency and confidence limit estimates from the underlying grids are extracted and the output is displayed directly below the map in three separate tabs: 'PF tabular', 'PF graphical' and 'Supplementary information'. A printer-friendly version of the precipitation frequency estimates with some supplementary information can be obtained by selecting the "Print Page" icon above the output display (see Figure 5.3.2). The printed page will include metadata information about the selected point in the header, tabular and graphical representations of the estimates, and maps of the location.

The 'PF tabular' tab provides data tables of the precipitation frequency depths (or intensities) showing also the lower and upper bounds of the 90% confidence interval. These data can be downloaded as comma-separated values (csv format) from a selection beneath the tables (see Figure 5.3.2).



PF tabular | PF graphical | Supplementary information | Print Page

PDS-based precipitation frequency estimates with 90% confidence intervals (in inches)[1]

Duration	Average recurrence interval (years)								
	1	2	5	10	25	50	100	200	500	1000

60-day	15.9 (14.1–18.3)	20.9 (18.5–24.0)	27.0 (23.9–31.1)	31.7 (27.9–36.8)	37.8 (32.3–45.1)	42.2 (35.5–51.2)	46.5 (38.3–57.6)	50.8 (40.9–64.3)	56.3 (43.8–73.8)	60.4 (45.7–81.4)

[1] Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.

Figure 5.3.2. Precipitation frequency data for a selected location in tabular format.

The 'PF graphical' tab has two sub-tabs. The first, 'Curves', shows two basic types of output based on the user's selection of data type: depth-duration-frequency (DDF) or intensity-duration-frequency (IDF) graphs. The PFDS provides DDF and IDF graphs in two different formats: with duration and with frequency on x-axis. An example of the DDF graph in both formats is given in Figure 5.3.3; an example of the IDF graph with duration on x-axis is shown in Figure 5.3.4. Both, DDF and IDF graphs can be built from either AMS or PDS data, depending on the user's selection of time series type. The second sub-tab, 'PF estimates with confidence intervals' shows plots of the precipitation magnitude-frequency curve with upper and lower confidence limits for a selected duration (see example in Figure 5.3.5).

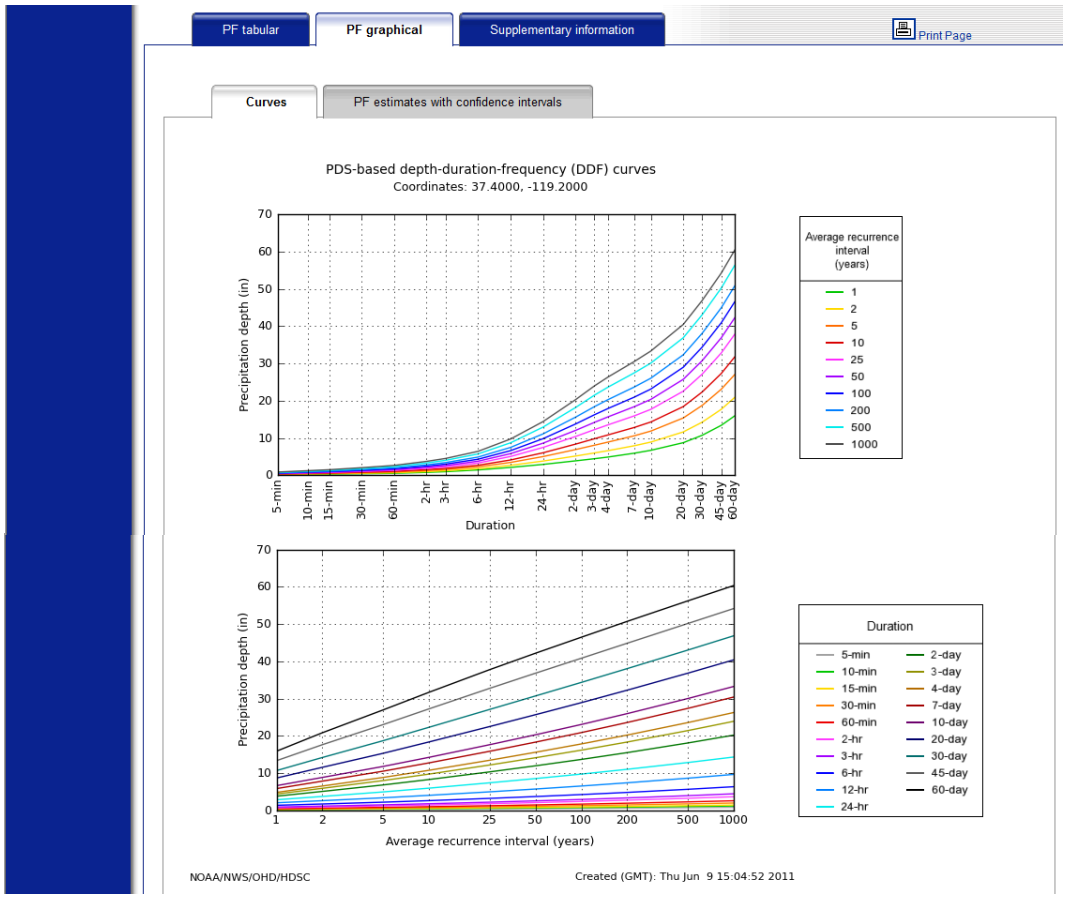

Figure 5.3.3. Sample depth-duration-frequency curves built from the PDS data with duration on the x-axis (top figure) and average recurrence interval on the x-axis (bottom figure).

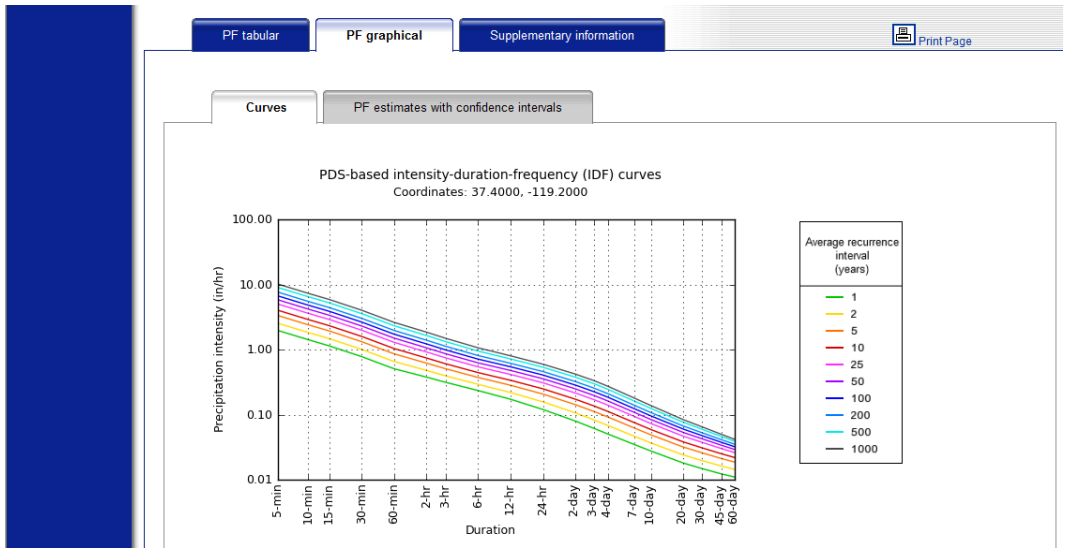

Figure 5.3.4. Sample intensity-duration-frequency (IDF) graph with duration on the x-axis.

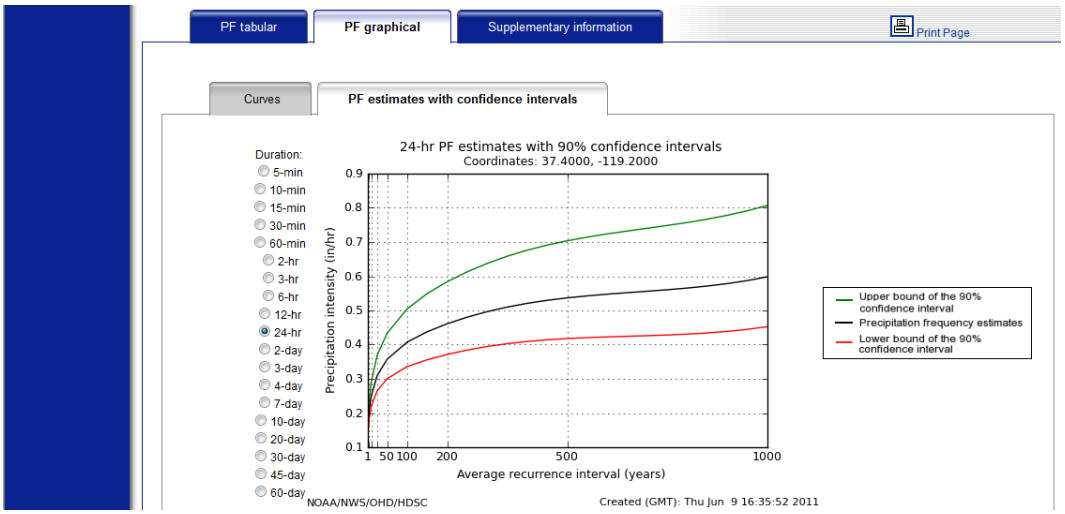

Figure 5.3.5. Sample of a magnitude-frequency plot with the upper and lower bounds of the 90% confidence interval for 24-hour duration.

Lastly, the 'Supplementary information' tab provides links to additional data and information for that location:

- **NOAA Atlas 14 Volume 6 document.**
- **Precipitation frequency grids in GIS compatible formats.** Grids are available for AMS- and PDS-based estimates for all combinations of durations and average recurrence intervals or annual exceedance probabilities, respectively (as shown in Tables 5.2.1 and 5.2.2). Users are advised to review the Federal Geographic Data Committee (FGDC) compliant metadata before using any of the GIS datasets (http://hdsc.nws.noaa.gov/hdsc/pfds/na14_vol6_ca_grid_metadata.html).

- **Cartographic maps of precipitation frequency estimates.** Cartographic maps show contour lines created from gridded PDS-based precipitation frequency estimates for selected durations and average recurrence intervals. Figure 5.3.6 shows an excerpt from a cartographic map. Maps were created to serve as visual aids and are not recommended for interpolating precipitation frequency estimates. Users are advised to retrieve point precipitation frequency values from the PFDS interface which accesses the gridded data directly.

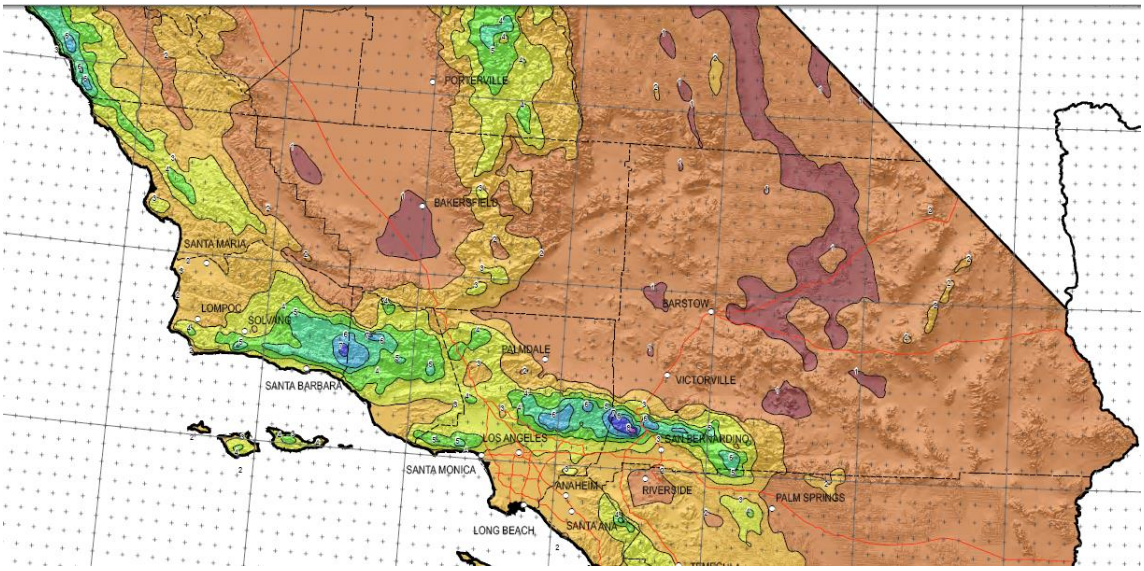

Figure 5.3.6. An excerpt of a cartographic map for 2-year ARI and 24-hour duration.

- **Temporal distributions of annual maxima.** Temporal distributions of AMS amounts are provided for 6-hour, 12-hour, 24-hour, and 96-hour durations for delineated climate regions. The temporal distributions for the duration are expressed in probability terms as cumulative percentages of precipitation totals. To provide detailed information on the varying temporal distributions, separate temporal distributions were derived for four precipitation cases defined by the duration quartile in which the greatest percentage of the total precipitation occurred. Figure 5.3.7 shows as an example the regional temporal distribution curves of all precipitation cases for the 6-hour and 24-hour durations. See Appendix A.6 for more information.
- **Seasonality analysis.** The seasonality graphs (an example is shown in Figure 5.3.8) show the percentage of annual maxima for a given duration that exceeded the NOAA Atlas 14 precipitation frequency estimates for the duration and selected annual exceedance probabilities in each month for various climate regions. Results are provided for the 60-minute, 24-hour, 2-day, and 10-day durations and for annual exceedance probabilities of 1/2, 1/5, 1/10, 1/25, 1/50, and 1/100. Seasonality graphs are not intended to be used to derive seasonal precipitation frequency estimates. See Appendix A.7 for more information.

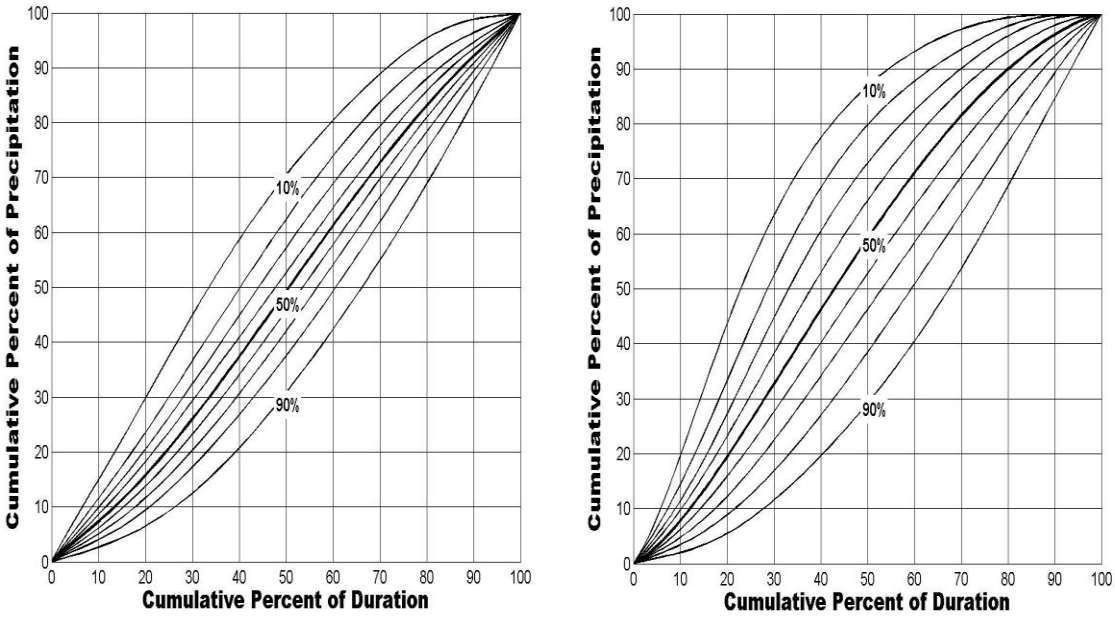

Figure 5.3.7. Sample temporal distribution curves for 6-hour (left panel) and 24-hour (right panel).

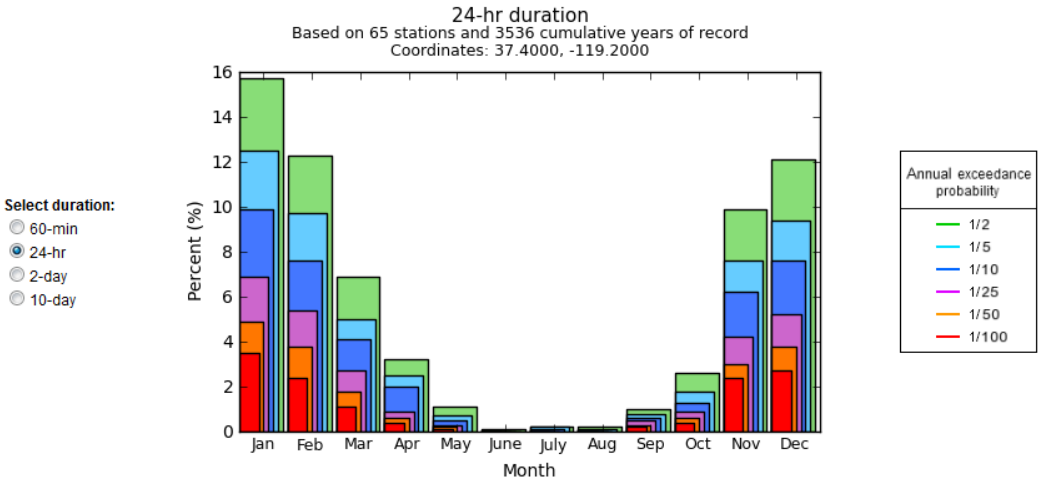

Figure 5.3.8. Sample 24-hour seasonal exceedance graph.

- **Rainfall frequency estimates.** PDS-based and AMS-based rainfall frequency estimates with 90% confidence intervals are provided for durations between 1 and 24 hours (Figure 5.3.9). Estimates are also available in csv format. For elevations below 3,000 feet, there is no difference between rainfall and precipitation frequency estimates. See Section 4.7 for more information.

VI. Rainfall frequency estimates

Rainfall (liquid precipitation only) frequency estimates are provided for durations between 1 and 24 hours in addition to precipitation frequency estimates. Please refer to NOAA Atlast 14 document for more information.

PDS-based rainfall frequency (RF) estimates with 90% confidence intervals (in inches/hour)[1]

Duration	Average recurrence interval (years)									
	1	2	5	10	25	50	100	200	500	1000
60-min	6.11 (5.27–7.15)	7.90 (6.80–9.24)	10.4 (8.89–12.2)	12.5 (10.6–14.8)	15.5 (12.7–19.3)	18.0 (14.3–23.0)	20.7 (16.0–27.2)	23.7 (17.6–32.1)	27.9 (19.8–39.9)	31.5 (21.4–46.9)
2-hr	4.54 (3.92–5.30)	5.74 (4.96–6.71)	7.44 (6.40–8.74)	8.92 (7.58–10.6)	11.1 (9.01–13.7)	12.8 (10.2–16.3)	14.7 (11.3–19.3)	16.8 (12.5–22.7)	19.8 (14.0–28.2)	22.3 (15.1–33.2)
3-hr	3.79 (3.27–4.42)	4.75 (4.10–5.56)	6.11 (5.26–7.17)	7.30 (6.20–8.67)	9.00 (7.34–11.2)	10.4 (8.26–13.2)	11.9 (9.18–15.6)	13.6 (10.1–18.4)	16.0 (11.3–22.8)	18.0 (12.2–26.8)
6-hr	2.78 (2.41–3.25)	3.47 (3.00–4.06)	4.45 (3.83–5.23)	5.32 (4.52–6.32)	6.53 (5.32–8.09)	7.52 (5.97–9.56)	8.58 (6.61–11.2)	9.73 (7.24–13.2)	11.4 (8.06–16.3)	12.8 (8.68–19.0)
12-hr	2.04 (1.77–2.39)	2.59 (2.24–3.03)	3.37 (2.90–3.96)	4.06 (3.46–4.82)	5.01 (4.09–6.19)	5.78 (4.59–7.35)	6.58 (5.07–8.63)	7.44 (5.54–10.1)	8.68 (6.14–12.4)	9.69 (6.57–14.4)
24-hr	1.14 (1.01–1.30)	1.51 (1.34–1.73)	2.07 (1.84–2.38)	2.59 (2.28–3.00)	3.30 (2.83–3.92)	3.89 (3.28–4.71)	4.51 (3.74–5.57)	5.18 (4.19–6.54)	6.21 (4.86–8.12)	7.03 (5.34–9.44)

[1] Rainfall frequency (RF) estimates in this table are based on frequency analysis of partial duration series (PDS).

Numbers in parenthesis are RF estimates at lower and upper bounds of the 90% confidence interval. The probability that rainfall frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.

Estimates from the table in csv format: Rainfall frequency estimates Submit

Figure 5.3.9. Rainfall frequency estimates for a selected location in tabular form.

- **Time series data.** Annual maximum series precipitation data used in frequency analysis is available only for gauged locations.
- **Information on nearby climate stations** (via NCDC).
- **Watershed information** (via the Environmental Protection Agency).

Some of the NOAA Atlas 14 data products can also be accessed through the left menu bar on the PFDS web page, including:

- ASCII grids of precipitation frequency estimates,
- cartographic maps,
- temporal distributions,
- annual maximum series (AMS) datasets,
- associated documentation.

Answers to frequently asked questions (FAQ) are available via links on the PFDS web site. Inquiries regarding the use of the PFDS or its data can be addressed by emailing HDSC.Questions@noaa.gov.

6. Peer review

A peer review of the California precipitation frequency project's preliminary results was carried out during an eight week period starting on July 22, 2010. The request for review was sent via email to the over 600 members of the HDSC list-server from all over the United States and other interested parties in California. Potential reviewers were asked to evaluate the reasonableness of point precipitation frequency estimates as well as their spatial patterns. The review included the following items:

a. List of all stations used in the analysis. The list included information on station name, state, source of data, assigned station ID, latitude, longitude, elevation, and period of record. It also showed information if the station was merged with another station, if the station was co-located with another station with a different ID, and if metadata at the station were changed.
b. List of all stations that were received by HDSC, but not considered in analysis. This list contained stations that were not used, either because there was another station with a longer period of record nearby, or station data were not reliable, or the station period of record was not long enough and it was not a candidate for merging with any nearby station.
c. At-station depth-duration-frequency curves for a range of durations for which annual maximum series data were extracted.
d. Spatially-interpolated maps of mean annual maxima for 60-minute, 24-hour and 10-day durations.
e. Precipitation frequency estimates for 60-minute, 24-hour and 10-day durations and for 2-year and 100-year average recurrence intervals.

The reviews provided critical feedback that improved estimates. Reviewers' comments regarding station metadata, at-station precipitation frequency estimates and their spatial patterns, and the web interface along with HDSC responses can be found in Appendix A.5.

7. Comparison with previous NOAA publications

The precipitation frequency estimates in NOAA Atlas 14 Volume 6 supersede the estimates for California previously published in the following publications:

a. *NOAA Atlas 14 Volume 1, Precipitation-Frequency Atlas of the United States, Semiarid Southwest* (Bonnin et al., 2004) for the southeastern semiarid areas of California for 5-minute to 60-day durations;
b. *Short Duration Rainfall Frequency Relations for California* (Frederick and Miller, 1979) for the remainder of California for 5-minute through 60-minute durations;
c. *NOAA Atlas 2 Volume 11, Precipitation Frequency Atlas of the Western United States, California* (Miller et al., 1973) for the remainder of California for 60-minute through 24-hour durations;
d. *Technical Paper No. 49, Two- to Ten-Day Precipitation for Return Periods of 2 to 100 Years in the Contiguous United States* (Miller, 1964) for the remainder of California for 2-day through 10-day durations.

Precipitation frequency estimates at 100-year average recurrence interval from NOAA Atlas 14 Volume 6 were examined in relation to corresponding estimates from NOAA Atlas 14 Volume 1 Version 4 for 60-minute and 24-hour durations for the semiarid southwest and with NOAA Atlas 2 Volume 11 estimates for 6-hour and 24-hour durations for the remainder of the state.

Comparison with NOAA Atlas 14 Volume 1 estimates for southeastern California. The maps in Figures 7.1 and 7.2 illustrate the differences in estimates for southeastern California between Volume 6 Version 2 and Volume 1 Version 4 for 60-minute and 24-hour durations at the 100-year average recurrence interval. On average, precipitation frequency estimates for the 60-minute duration for the whole area decreased by 0.21 inches; at specific locations estimates changed between -1.11 and 1.61 inches. 100-year 24-hour precipitation frequency estimates changed between -8.71 and 6.38 inches, and, on average, increased by 0.24 inches for the whole project area.

The differences in estimates between the two volumes are attributed to: 1) the increase in number of stations used in frequency analysis, especially for sub-daily durations, 2) improved data quality control procedures, and 3) improved regional frequency analysis approach. Details on the quality control techniques used on Volume 6 can be found in Section 4.5 and new regional approach is described in Section 4.6.2. Details on approaches used in Volume 1 are presented in the document which is available online (www.nws.noaa.gov/oh/hdsc/PF_documents/Atlas14_Volume1.pdf).

It should also be noted that precipitation frequency estimates in Volume 6 at the California border were not adjusted to make a smooth transition from Volume 6 estimates for California to Volume 1 estimates for Nevada and Arizona.

Comparison with NOAA Atlas 2 estimates for the remainder of California. Differences in 100-year estimates between NOAA Atlas 14 Volume 6 Version 2 and NOAA Atlas 2 Volume 11 were investigated for 6-hour and 24-hour durations, since gridded estimates for NOAA Atlas 2 were available only for those two durations; they are shown in the maps in Figures 7.3 and 7.4.

100-year 6-hour precipitation frequency estimates changed between -2.95 and 3.50 inches; on average, precipitation frequency estimates in NOAA Atlas 14 Volume 6 are about 0.24 inches higher. 100-year 24-hour precipitation frequency estimates changed between -8.63 and 9.00 inches, but on average, estimates increased only by 0.04 inches.

The greatest differences between the two Atlases were observed at ungaged locations therefore due to the type of spatial interpolation used in each project. In addition, different frequency analysis approaches were used in two projects. Finally, there were considerably more stations with longer periods of record lengths available for frequency analysis for NOAA Atlas 14. NOAA Atlas 2 estimates were developed in 1973, so almost 40 additional years of data were available for the update in 2011. A total of 1,294 stations with between 17 to 141 data years were available for the whole state of California for frequency analysis of the 24-hour duration in NOAA Atlas 14, while only 806 daily stations with periods of record (data years may be shorter due to missing data at stations) ranging from 10 to 94 years were used in NOAA Atlas 2.

Regarding hourly durations, frequency estimates in NOAA Atlas 2 were developed from 396 stations and only for the 6-hour duration; ratios were applied to generate 1-hour and 12-hour durations. All but two hourly stations used in NOAA Atlas 2 had fewer than 44 years of record. In contrast, for NOAA Atlas 14, 413 hourly stations with between 17 and 101 data years were directly used in the analysis for all hourly durations.

Finally, frequency estimates for 2-day to 10-day durations published in 1964 in Technical Paper 49, were obtained from only 10 stations in California with 49 years of record on average (an additional 40 stations with at least 18 years of data were used indirectly to develop relationships between 1-day and 10-day frequency estimates). In comparison, all 1,294 stations used for 24-hour duration frequency analysis, were also used in the NOAA Atlas 14 frequency analysis for longer daily durations.

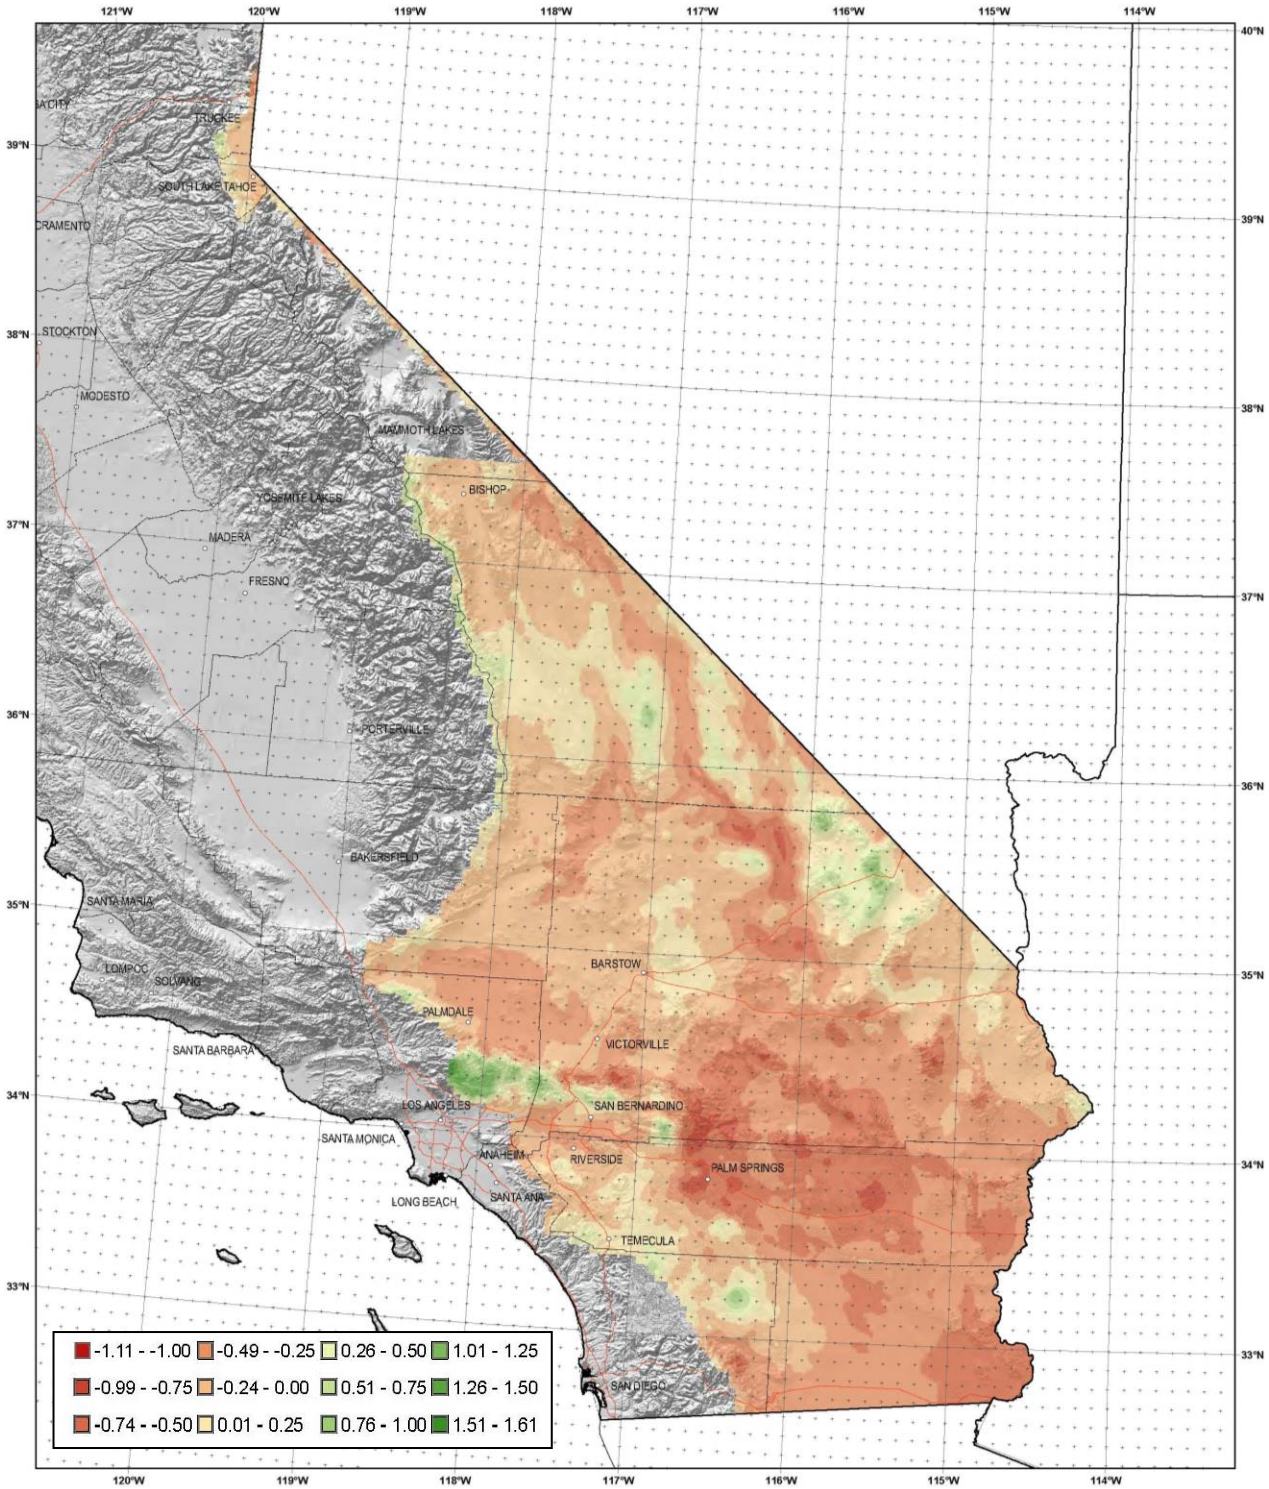

Figure 7.1. Differences in 100-year 60-minute estimates (in inches) between Volume 6 Version 2 and Volume 1 Version 4 for southeast California.

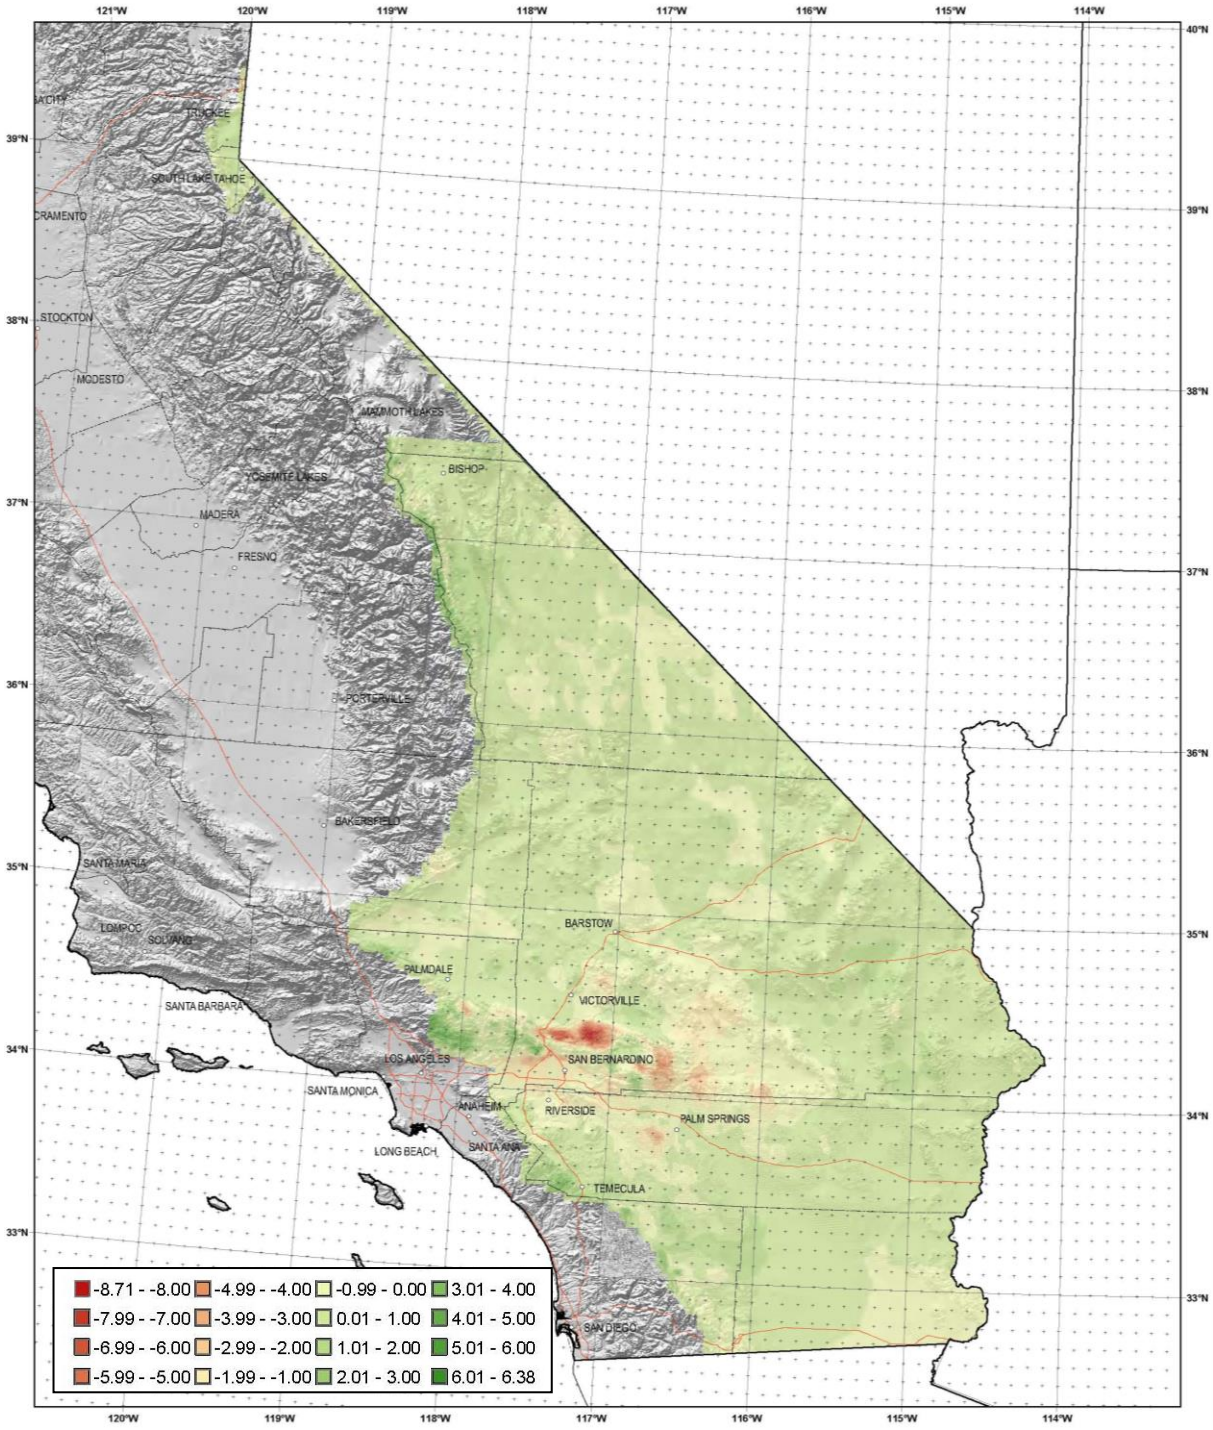

Figure 7.2. Differences in 100-year 24-hour estimates (in inches) between Volume 6 Version 2 and Volume 1 Version 4 for southeast California.

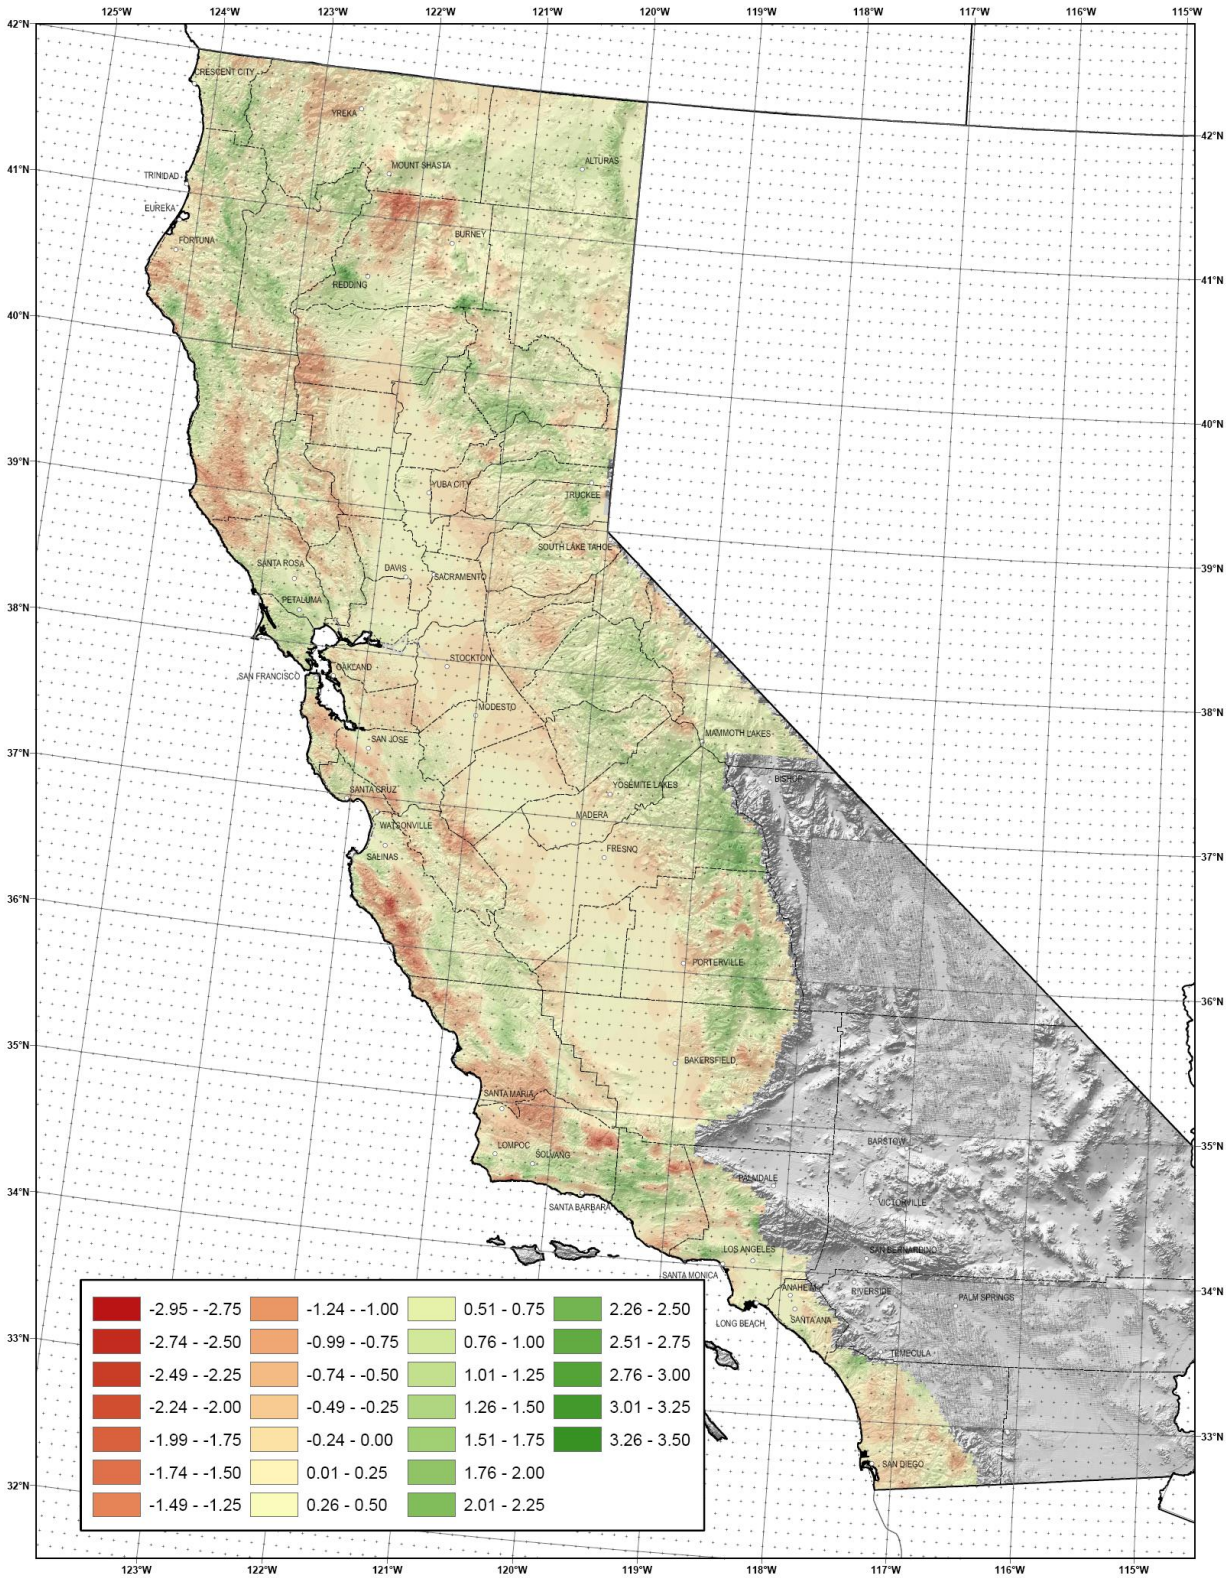

Figure 7.3. Differences in 100-year 6-hour estimates (in inches) between Volume 6 Version 2 and NOAA Atlas 2 Volume 11 for the remainder of California.

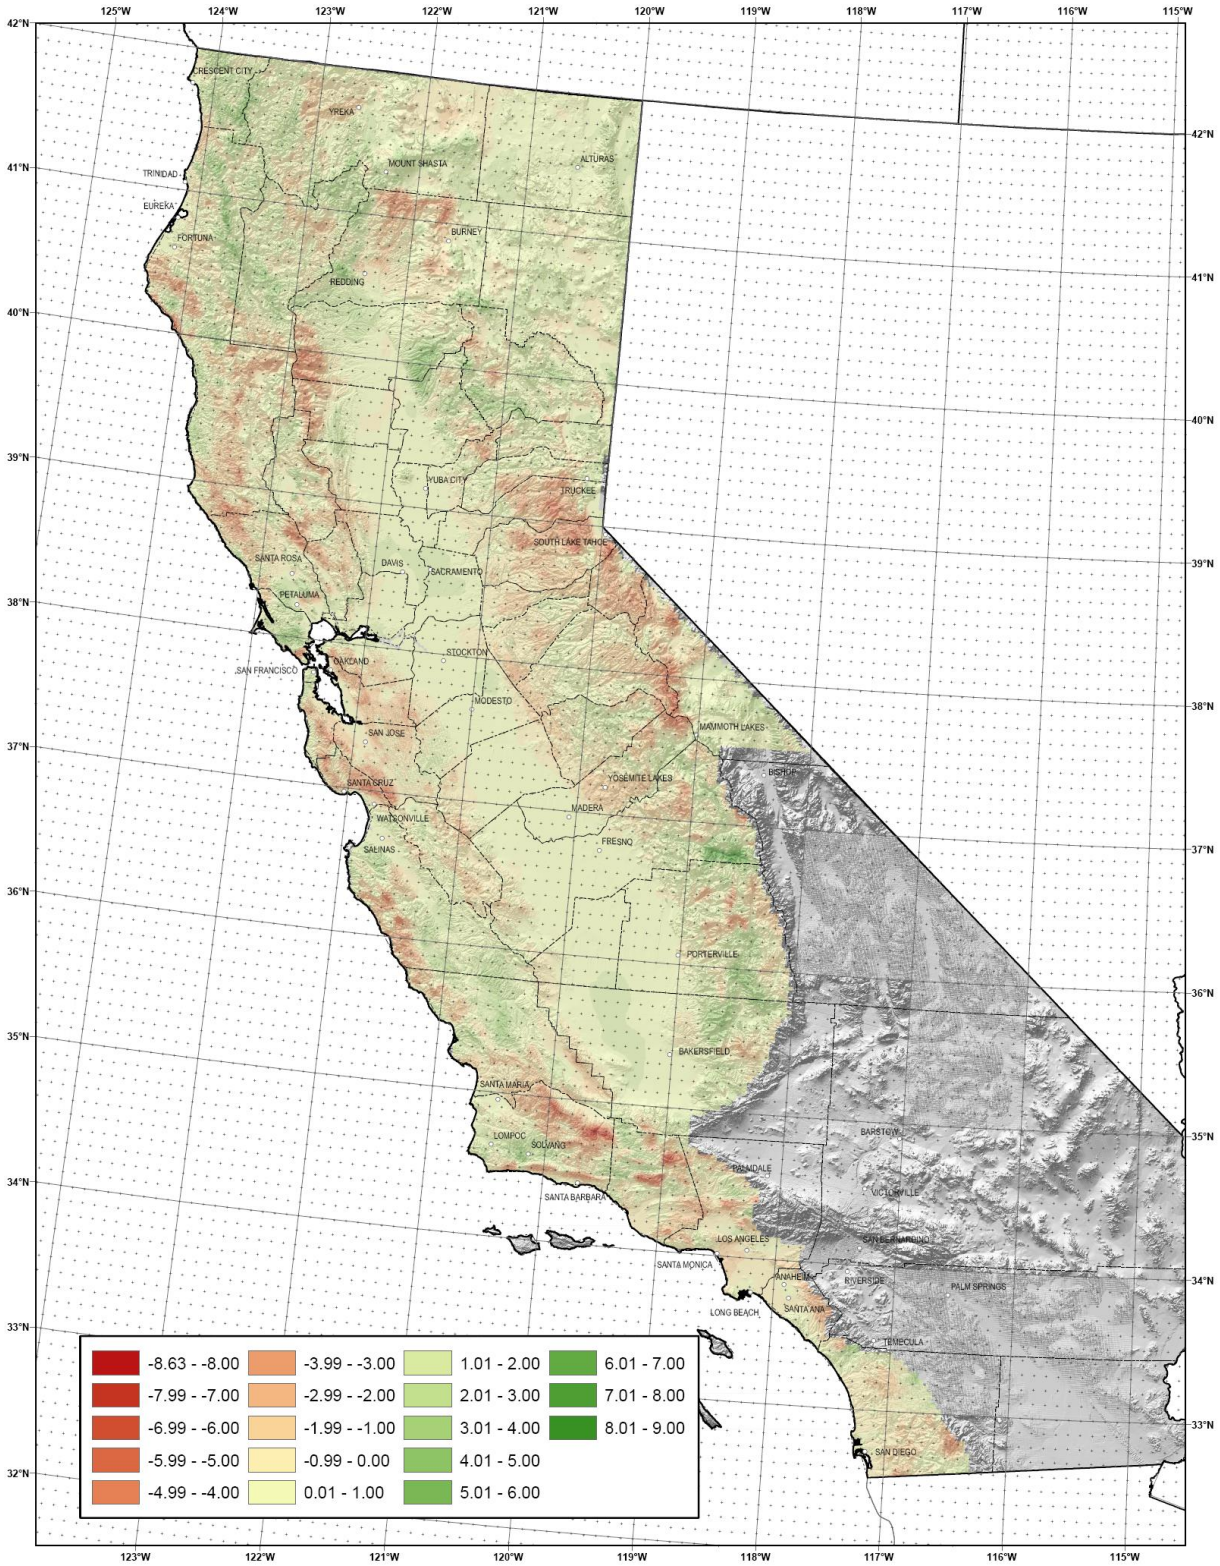

Figure 7.4. Differences in 100-year 24-hour estimates (in inches) between Volume 6 Version 2 and NOAA Atlas 2 Volume 11 for the remainder of California.

Acknowledgments

This work was funded by NOAA's National Weather Service, Office of Hydrologic Development, the California Department of Transportation and California Department of Water Resources, the U.S. Army Corps of Engineers, and the Coastal Storms Program of NOAA's National Ocean Service.

We acknowledge the many colleagues who provided additional data for this project beyond what was available from NOAA's National Climatic Data Center, including: Rand Allan of San Diego County Flood Control District; Jan Ballew of U.S. Army Corps of Engineers, Sacramento District; Mark Bandurraga of Ventura County Watershed Protection District; Mark Boucher and Scott McQuarrie of Contra Costa County Flood Control and Water Conservation District; Steven Clark of Riverside County Flood Control and Water Conservation District; Frank Codd of Alameda County Flood Control District; Neal Conatser of Marin County Department of Public Works; Randy Forby of San Bernardino County Flood Control District; retired state climatologist Jim Goodridge; Rob Hartman of California Nevada River Forecast Center; Don Laurine of Northwest River Forecast Center; Matt Naftaly of County of Santa Barbara, Flood Control and Water Conservation District; Rob Nelson of City of Roseville, Department of Public Works; Eric Olson of Santa Clara Valley Water District; Bryan Pastor of Orange County Public Works, Orange County Watersheds; Tawnly Pranger of CA Department of Water Resources; Jim Asby of Western Regional Climate Center; Brent Sunamoto of Fresno Metropolitan Flood Control District; Tom Smythe of Lake County Department of Public Works; Ken Stumpf of Santa Clara Valley Water District; and Ben Willardson of Los Angeles County, Department of Public Works. Special thanks to Claire Trower of Honeydew, CA who provided us with data collected by herself and her late husband, Dan, since 1980 along Wilder Ridge which is an area of extreme precipitation in California.

Lastly, we acknowledge colleagues who provided feedback to improve the final product, including: Mark Bandurraga of Ventura County Watershed Protection District; Mark Boucher of Contra Costa County Flood Control and Water Conservation District; Neal Conatser of Marin County Department of Public Works; Paul Davies, Kerry Molz, Curt Whiteaker, and Kemset Moore of the Office of State Highway Drainage Design, California Department of Transportation; John High of the U.S. Army Corps of Engineers; William Merkel of United States Department of Agriculture's National Resources Conservation Service; and Zhida Song-James of Michael Baker Ir. Inc.

Appendix A.1 List of stations used to prepare precipitation frequency estimates

Table A.1.1. List of stations in the state of California used in the analysis showing station name, station ID, post-merge station ID, base duration, source of data, latitude, longitude, elevation, and period of record. Bold font in the latitude, longitude, and elevation fields indicates information that has been adjusted. Bold font in the 'Period of record' field indicates that the station data was extended using data from station that has the same ID in 'Post-merge station ID' column.

Table A.1.2. List of stations in the buffer states of Arizona, Nevada and Oregon used in the analysis showing station name, station ID, post-merge station ID, base duration, source of data, latitude, longitude, elevation, and period of record. Bold font in the latitude, longitude, and elevation fields indicates information that has been adjusted. Bold font in the 'Period of record' field indicates that the station data was extended using data from station that has the same ID in 'Post-merge station ID' column.

Table A.1.3. List of stations used in the analysis for n-minute scaling factors (see Section 4.6.3) showing station name, state, station ID, source of data, latitude, longitude, elevation, and period of record. Bold font in the latitude, longitude, and elevation fields indicates information that has been adjusted.

Appendix A.2 Annual maximum series trend analysis

1. Selection of statistical tests for detection of trends in AMS

Precipitation frequency analysis methods used in NOAA Atlas 14 volumes are based on the assumption of stationary climate over the period of observation (and application). To meet the stationarity criterion, the annual maximum series data must be free from trends during the observation period. A number of parametric and non-parametric statistical tests are available for the detection and/or quantification of trends. Selection of an appropriate statistical test requires consideration of the data tested and the limitations of the test.

Annual maximum series (AMS) were first graphed for each station in the project area to examine the time series and to observe general types of trends in the data. Visual inspection of time series plots indicated that there were no abrupt changes or apparent cycles in the AMS, but suggested the possibility of slight trends at some locations. Changes appeared to be gradual and approximately linear.

The null hypothesis that there are no trends in annual maximum series was tested on 1-hour and 1-day AMS data at each station in the project area with at least 50 years of data. The hypothesis was tested at each station separately and for the state as a whole at the level of significance $\alpha = 5\%$. At-station trends were inspected using the parametric *t*-test for trend and non-parametric Mann-Kendall test (Maidment, 1993). Both tests are extensively used for trend analysis in environmental sciences and are appropriate for records that have undergone a gradual change. The tests are fairly robust, readily available, and easy to use and interpret. Since each test is based on different assumptions and different test statistics, the rationale was that if both tests have similar outcomes there can be more confidence about the results. If the outcomes were different, it would provide an opportunity to investigate reasons for discrepancies.

Parametric tests in general have been shown to be more powerful than non-parametric tests when the data are approximately normally distributed and when the assumption of homoscedasticity (homogeneous variance) holds (Hirsch et al., 1991), but are less reliable when those assumptions do not hold. The parametric *t*-test for trend detection is based on linear regression, and therefore checks only for a linear trend in data. A linear trend assumption seemed adequate here, since, time series plots indicated if any, monotonic,linear changes in AMS. The Pearson correlation coefficient (r) was used as a measure of linear association for the *t*-test. The hypothesis that the data are not dependent on time (and also that they are independent and normally distributed values) was tested using the test statistic t that follows Student's distribution as defined as:

$$t = \frac{r\sqrt{n-2}}{\sqrt{1-r^2}}$$

where n is the record length of the AMS. The hypothesis is rejected when the absolute value of the computed *t*-statistic is greater than the critical value obtained from Student's distribution with (n - 2) degrees of freedom and exceedance probability of $\alpha/2$ %, where α is the significance level. The sign of the *t*-statistic defines the direction of the trend, positive or negative.

Non-parametric tests have advantages over parametric tests since they make no assumption of probability distribution and are performed without specifying whether trend is linear or nonlinear. They are also more resilient to outliers in data because they do not operate on data directly. One of the disadvantages of non-parametric tests is that they do not account for the magnitude of the data. The Mann-Kendall test was selected among various non-parametric tests because it can accommodate missing values in a time series, which was a frequent occurrence in the AMS data. The Mann-Kendall test compares the relative magnitudes of annual maximum data. If annual maximum values

are indexed based on time, and x_i is the annual maximum value that corresponds to year t_i, then the Mann-Kendall statistic is given by:

$$S = \sum_{k=1}^{n-1} \sum_{i=k+1}^{n} sign(x_i - x_k)$$

The test statistic Z is then computed using a normal approximation and standardization of the statistic S. The null hypothesis that there is no trend in the data is rejected at significance level α if the computed Z value is greater, in absolute terms, than the critical value obtained from standard normal distribution that has probability of exceedance of $\alpha/2$ %. The sign of the statistic defines the direction of the trend, positive or negative.

In addition to an at-station trend analysis, the relative magnitude of any trend in AMS for the state as a whole was assessed by linear regression techniques. 1-hour and 1-day station-specific AMS for stations with at least 50 years of data were rescaled by corresponding mean annual maximum values and then regressed against time, where time was defined as year of occurrence minus 1900. The regression results from all stations were tested against a null hypothesis of zero serial correlation (zero regression slopes).

2. Trend analysis results and conclusion

The null hypothesis that there are no trends in annual maximum series was tested on 1-hour and 1-day AMS data at each station in the project area with at least 50 years of data. 91 hourly and 734 daily stations satisfied the record length criterion. The *t*-test and Mann-Kendall test for trends were applied to test the hypothesis. Results from both tests were very similar. Both tests indicated no statistically-significant trends in about 86% of hourly and 92% of daily stations (details in Table A.2.1). Tests detected positive trends in 14% of hourly and 5% of daily stations. No negative trends were detected in hourly data, and they were present in about 3% of daily AMS. Spatial distribution of Mann-Kendall trend analysis results for 1-day AMS is shown in Figure A.2.1 and for 1-hour AMS in Figure A.2.2.

Table A.2.1. Trend analysis results based on *t*-test and Mann-Kendall (M-K) test for 1-hour and 1-day AMS data.

Number of stations	**1-hour**		**1-day**	
	***t*-test**	**M-K test**	***t*-test**	**M-K test**
no trend	77	78	668	671
positive trend	14	13	32	38
negative trend	0	0	34	25
total	91	91	734	734

Results from the regional trend analysis also indicated that the null hypothesis that there are no trends in AMS in the state of California as a whole could not be rejected at 5% significance level. Because tests at both, 1-hour and 1-day durations indicated no statistically-significant trends in the data, the assumption of stationary climate was accepted for this project area and no adjustment to AMS data was recommended.

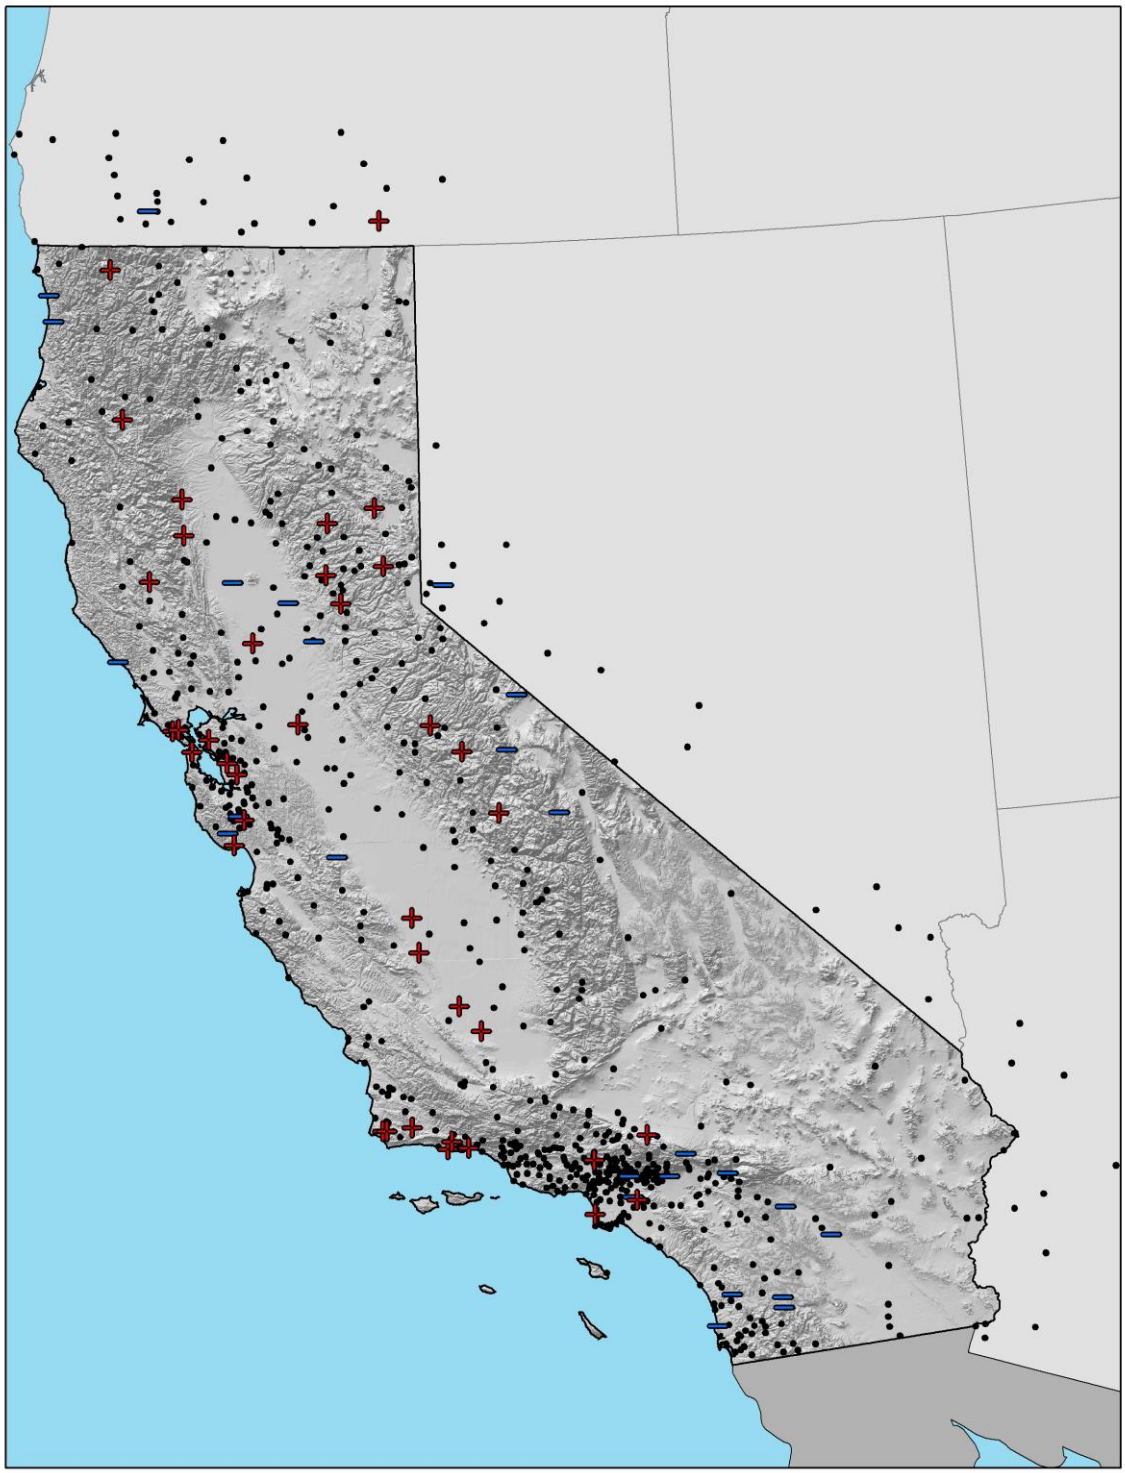

Figure A.2.1. Spatial distribution of Mann-Kendall test's trend results for 1-day AMS. Red plus signs indicate locations where the test detected positive trends in AMS data and blue negative signs indicate locations with negative trends.

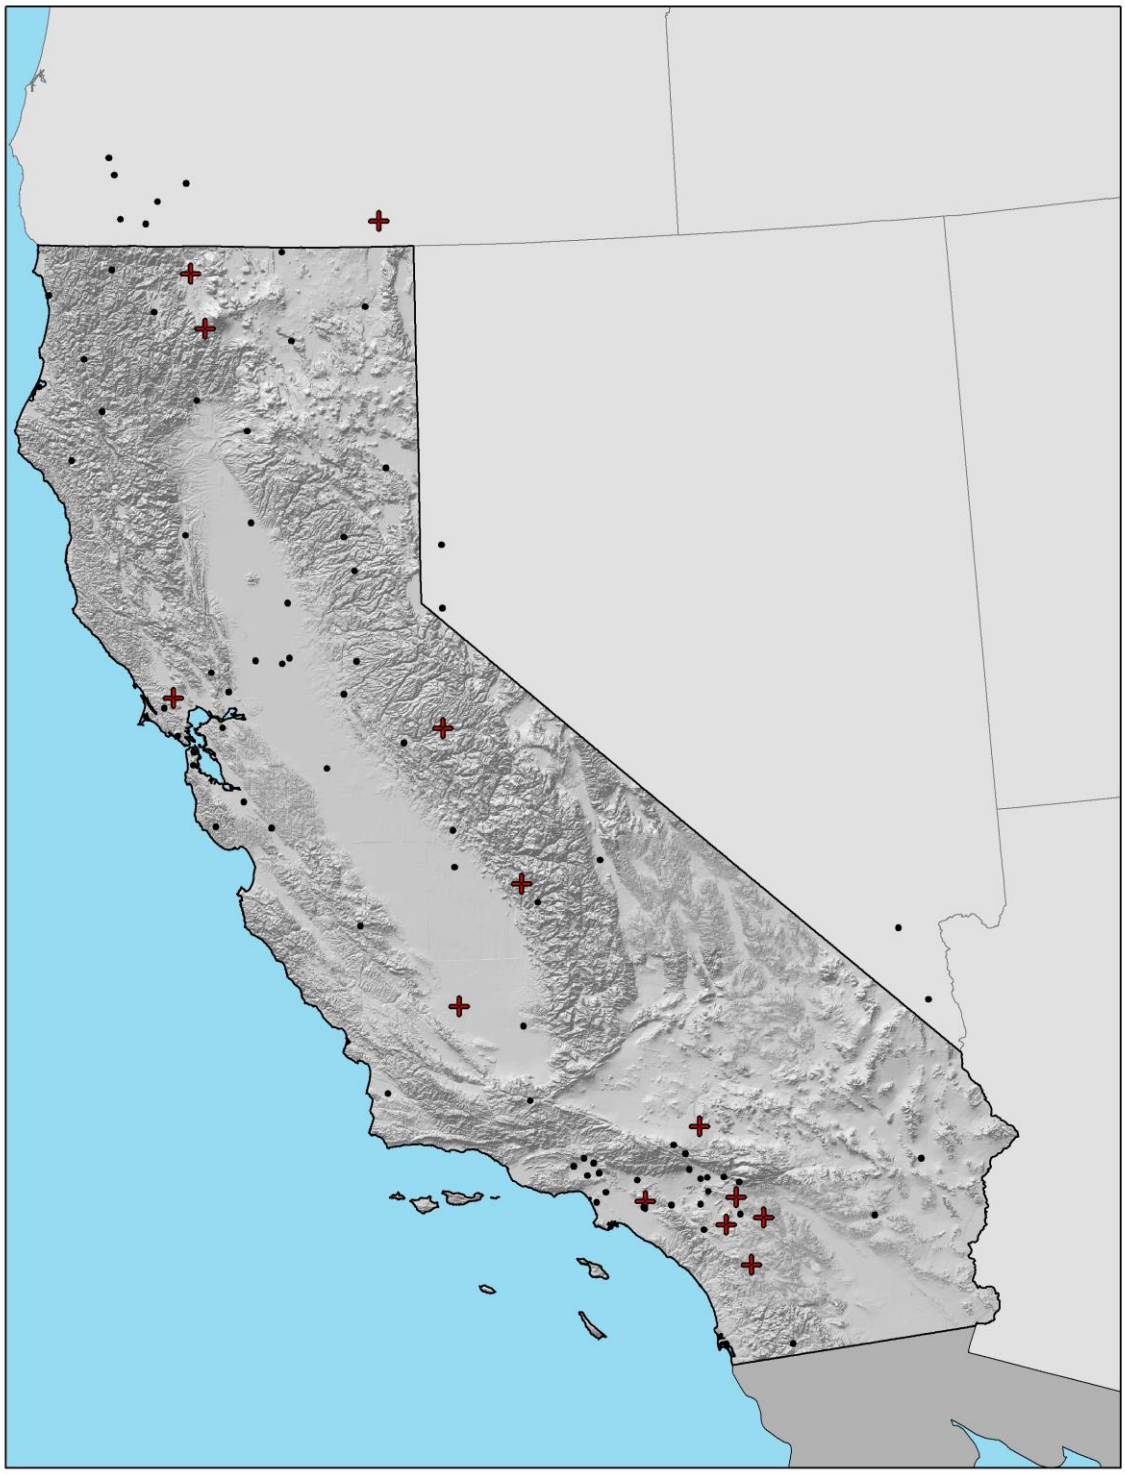

Figure A.2.2. Same as Figure A.2.1 but for 1-hour duration.

Appendix A.3 List of L-moments (λ_1, λ_2, λ_3) for 1-hour through 60-day durations

Table A.3.1. λ_1 moments.

Appendix A.4 PRISM report
(report was formatted by HDSC)

Final Report

Production of Precipitation Frequency Grids for California Using a Specifically Optimized PRISM System

Prepared for
National Weather Service, Hydrologic Design Service Center
Silver Spring, Maryland

Prepared by
Christopher Daly
PRISM Climate Group
Oregon State University

April 2011

1. Project goal

The Hydrometeorological Design Studies Center (HDSC) within the Office of Hydrologic Development of NOAA's National Weather Service is updating precipitation frequency estimates for California. In order to complete the spatial interpolation of point estimates, HDSC requires spatially interpolated grids of MAM (Mean Annual Maximum) precipitation. The contractor, the PRISM Climate Group at Oregon State University (OSU), was tasked with producing a series of grids for precipitation frequency estimation using an optimized system based on the Parameter-elevation Regressions on Independent Slopes Model (PRISM) and HDSC-calculated point estimates for the state of California.

2. Background

HDSC used L-moment based regional frequency analysis approach to estimate precipitation frequencies. In this approach, the mean of the underlying precipitation frequency distribution is estimated at point locations with a sufficient history of observations. The form of the distribution and its parameters are estimated regionally. Once the form of the distribution has been selected and its parameters have been estimated, precipitation frequency estimates can be computed from grids of the MAM. The grids that are the subject of this report are spatially interpolated grids of the point estimates of the MAM for various precipitation durations. The point estimates of the MAM were provided by HDSC. HDSC selected an appropriate precipitation frequency distribution along with regionally estimated parameters and used this information with the grids of the MAM to derive grids of precipitation frequency estimates.

The PRISM Climate Group has previously performed similar work to produce spatially interpolated MAM grids for updates of precipitation frequency estimates in the Semiarid Southwest United States, the Ohio River Basin and Surrounding States, Puerto Rico/US Virgin Islands, and Hawaiian Islands study areas.

3. Report

This report describes tasks performed to produce draft mean annual maximum (MAM) grids for 17 precipitation durations: 15 and 30 minutes; 1, 2, 3, 6, and 12 hours; and 1, 2, 3, 4, 7, 10, 20, 30, 45, and 60 days for CA. The 15 and 30-minute and 3-day durations were new, having not been modeled before. The tasks described were not necessarily performed in the order described, nor were they performed just once. The process was dynamic and had numerous feedbacks.

3.1. Adapting the PRISM system

The PRISM modeling system was adapted for use in this project after a small investigation was performed for the Semiarid Southwest United States, and subsequently used in the Ohio River Basin and Surrounding States, Puerto Rico/Virgin Islands, and Hawaiian Islands study areas. This investigation and adaptation procedure is summarized below.

PRISM is a knowledge-based system that uses point data, a digital elevation model (DEM), and many other geographic data sets to generate gridded estimates of climatic parameters (Daly et al. 1994, 2002, 2003, 2006, 2008) at monthly to daily time scales. Originally developed for precipitation estimation, PRISM has been generalized and applied successfully to temperature, among other parameters. PRISM has been used extensively to map precipitation, dew point, and minimum and maximum temperature over the United States, Canada, China, and other countries. Details on PRISM formulation can be found in Daly et al. (2002, 2003, 2008), which are available from http://prism.oregonstate.edu/docs/.

Adapting the PRISM system for mapping precipitation frequencies required an approach slightly different than the standard modeling procedure. The amount of station data available to HDSC for precipitation frequency was much less than that available for high-quality precipitation maps, such as the peer-reviewed PRISM 1971-2000 mean precipitation maps (Daly et al. 2008). Data sources suitable for long-term mean precipitation but not for precipitation frequency included snow courses, short-term COOP stations, remote storage gauges, and others. In addition, data for precipitation durations of less than 24 hours were available from hourly precipitation stations only. This meant that mapping precipitation frequency using HDSC stations would sacrifice a significant amount of the spatial detail present in the 1971-2000 mean precipitation maps.

A pilot project to identify ways of capturing more spatial detail in the precipitation frequency maps was undertaken. Early tests showed that mean annual precipitation (MAP) was an excellent predictor of precipitation frequency in a local area, much better than elevation, which is typically used as the underlying, gridded predictor variable in PRISM applications. In these initial tests, the DEM, the predictor grid in PRISM, was replaced by the official USDA digital map of MAP for the lower 48 states (USDA-NRCS 1998, Daly et al. 2000). Detailed information on the creation of the USDA PRISM precipitation grids is available from Daly and Johnson (1999). MAP was found to have superior predictive capability over the DEM for locations in the southwestern US. The relationships between MAP and precipitation frequency were strong because many of the effects of various physiographic features on mean precipitation patterns had already been incorporated into the MAP grid from PRISM. Preliminary PRISM maps of 2-year and 100-year, 24-hour precipitation were made for the Semiarid Southwest and compared to hand-drawn HDSC maps of the same statistics. Differences were minimal, and mostly related to differences in station data used.

Further investigation found that the square-root transformation of MAP produced somewhat more linear, tighter and cleaner regression functions, and hence, more stable predictions, than the untransformed values; this transformation was incorporated into subsequent model applications. Square-root MAP was a good local predictor of not only longer-duration precipitation frequency statistics, but for short-duration statistics, as well. Therefore, it was determined that a modified PRISM system that used

square-root MAP as the predictive grid was suitable for producing high-quality precipitation frequency maps for this project.

For this study, an updated official USDA grid of MAP for CA (1971-2000 average) was used (Figure 1). This grid was developed under funding from the USDA Natural Resources Conservation Service, and is described in Daly et al. (2008).

3.2. PRISM configuration and operation for California

In general, PRISM interpolation consists of a local moving-window regression function between a predictor grid and station values of the element to be interpolated. The regression function is guided by an encoded knowledge base and inference engine (Daly et al., 2002, 2008). This knowledge base/inference engine is a series of rules, decisions and calculations that set weights for the station data points entering the regression function. In general, a weighting function contains knowledge about an important relationship between the climate field and a geographic or meteorological factor. The inference engine sets values for input parameters by using default values, or it may use the regression function to infer grid cell-specific parameter settings for the situation at hand. PRISM acquires knowledge through assimilation of station data, spatial data sets such as MAP and others, and a control file containing parameter settings.

The other center of knowledge and inference is that of the user. The user accesses literature, previously published maps, spatial data sets, and a graphical user interface to guide the model application. One of the most important roles of the user is to form expectations for the modeled climatic patterns, i.e., what is deemed "reasonable." Based on knowledgeable expectations, the user selects the station weighting algorithms to be used and determines whether any parameters should be changed from their default values. Through the graphical user interface, the user can click on any grid cell, run the model with a given set of algorithms and parameter settings, view the results graphically, and access a traceback of the decisions and calculations leading to the model prediction.

For each grid cell, the moving-window regression function for MAM vs. MAP took the form

$$\text{MAM value} = \beta_1 * \text{sqrt}(\text{MAP}) + \beta_0 \quad (1)$$

where β_1 is the slope and β_0 is the intercept of the regression equation, and MAP is the grid cell value of mean annual precipitation.

Upon entering the regression function, each station was assigned a weight that is based on several factors. For PRISM MAP mapping (used as the predictor grid in this study), the combined weight of a station was a function of distance, elevation, cluster, vertical layer, topographic facet, coastal proximity, and effective terrain weights, respectively. A full discussion of the general PRISM station weighting functions is available from Daly et al. (2008).

Given that the MAP grid incorporated detailed information about the complex spatial patterns of precipitation, only a subset of these weighting functions was needed for this study. For California, the combined weight of a station was a function of distance and clustering, respectively. A station is down-weighted when it is relatively from the target grid cell, or when it is clustered with other stations (which can lead to over-representation).

The moving-window regression function was populated by station data provided by the HDSC. A PRISM GUI snapshot of the moving-window relationship between MAP and 24-hour MAM in southern California is shown in Figure 2.

There were relatively few stations with data for durations of 12 hours or less from which to perform the interpolation. In addition, it was clear that the spatial patterns of durations of 12 hours or less could be very different than those of durations of 24 hours or more. This issue was encountered in a previous study for Puerto Rico. During that study the following procedure was developed, and adopted here:

(1) Convert available ≤ 12-hour station values to an MAM/24-hr MAM ratio (termed R24) by dividing by the 24-hour values;

(2) using the station R24 data in (1), interpolate R24 values for each ≤ 12-hour duration (15, 30, and 60 minutes; and 2, 3, 6, and 12 hours) using PRISM in inverse-distance weighting mode;

(3) using bi-linear interpolation from the cells in the R24 grids from (2), estimate R24 at the location of each station having data for ≥ 24-hour durations only;

(4) multiply the estimated R24 values from (3) by the 24-hour value at each ≥ 24-hour station to obtain estimated ≤ 12-hour values;

(5) append the estimated stations from (4) to the ≤ 12-hour station list to generate a station list that matches the density of that for ≥ 24 hours; and

(6) interpolate MAM values for ≤ 12-hour durations with PRISM, using MAP as the predictor grid.

Investigation of the little available data failed to provide convincing evidence that the spatial patterns of R24 values were strongly affected by coastal proximity, topographic facets, or other factors. Therefore, the slope of the moving-window regression function for R24 vs. MAP of the form

$$R24 = \beta_1 * \text{sqrt}(MAP) + \beta_0 \quad (2)$$

was forced to zero everywhere. This meant that the interpolated value of R24 was a function of distance and cluster weighting only (essentially inverse-distance weighting).

Relevant PRISM parameters for applications to 60-minute R24 and 24-hour MAM statistics are listed in Tables 1 and 2, respectively. Further explanations of these parameters and associated equations are available in Daly et al. (2002, 2008).

The values of radius of influence (*R)*, the minimum number of total (s_t) stations required in the regression were based on information from user assessment via the PRISM graphical user interface, and on a jackknife cross-validation exercise, in which each station was deleted from the data set one at a time, a prediction made in its absence, and mean absolute error statistics compiled (see Results section).

The input parameter that changed readily among the various durations was the default slope (β_{1d}) of the regression function. Slopes are expressed in units that are normalized by the average observed value of the precipitation in the regression data set for the target cell. Evidence gathered during PRISM model development indicates that this method of expression is relatively stable in both space and time (Daly et al. 1994).

Bounds are put on the slopes to minimize unreasonable slopes that might occasionally be generated due to local station data patterns; if the slope is out of bounds and cannot be brought within bounds by the PRISM outlier deletion algorithm, the default slope is invoked (Daly et al., 2002). The maximum slope bound was set to a uniformly high value of 30.0, to accommodate a large range of valid slopes; lower values were not needed to handle extreme values, because all values were within reasonable ranges. Slope default values were based on PRISM diagnostics that provided information on the distribution of slopes across the modeling region. The default value was set to approximate the average regression slope calculated by PRISM. For these applications, default slopes typically increased with increasing duration (Table 3). In general, the longer the duration, the larger the slope. This is primarily a result of higher precipitation amounts at the longer durations, and the tendency for longer-duration MAM statistics to bear a stronger and steeper relationship with MAP than shorter-duration statistics.

3.3. Preparation and review of draft grids

Draft grids for the 60-minute, 12-hour, 24-hour and 10-day durations were produced and made available to HDSC for evaluation. All of the necessary station data were provided by HDSC. The process began with a careful scrutiny of the station data and PRISM behavior. A version of PRISM which predicts for stations locations in the absence of each station (termed jackknifing) was run, and stations that were difficult for PRISM to predict for were identified, and sent to HDSC for review. HDSC removed the

stations, modified their values, or determined that the stations were accurate as-is. This process was performed iteratively, until an acceptable station data set was produced. The draft PRISM grids were subsequently completed and submitted to HDSC for review.

HDSC submitted the draft PRISM grids for external review. They received a comment from Marin County that the precipitation patterns were not sufficiently detailed to completely represent the orographic patterns in their county. Marin County provided additional station data, which were incorporated into subsequent drafts.

3.4. Final grids

Having found the revised draft grids acceptable, HDSC requested that grids for all durations be completed. At this time, three additional durations (not in the original work plan) were requested: 15 and 30 minutes, and 3 days. Before delivering the final grids to HDSC, the PRISM Climate Group checked them for internal consistency. In other words, the value of the MAM at each grid point for each duration must be greater than the value for shorter durations at the same grid point. If an inconsistency of this nature occurs, the current convention is to start with the 24 duration as a baseline, and set longer durations to slightly higher values and shorter durations to slightly lower values. A small consistency adjustment was needed in only one location in the desert east of the Sierra Nevada, where very low precipitation amounts created very small differences in values between adjacent durations.

The final delivered grids inherited the spatial resolution of the latest 1971-2000 PRISM mean annual precipitation grids for California, which is 30 arc-seconds (~800 meters). The grid cell units are in mm*100. Final MAM grids delivered to HDSC are as follows:

15-minute
30-minute
60-minute
2-hour
3-hour
6-hour
12-hour
24-hour
48-hour
3-day
4-day
7-day
10-day
20-day
30-day
45-day
60-day

Total: 17

3.5. Performance evaluation

PRISM cross-validation statistics for 60-minute/24-hour MAM ratio and the 60-minute and 24-hour MAM intensities were compiled and summarized in Table 4. These errors were estimated using an omit-one jackknife method, where each station is omitted from the data set, estimated in its absence, then replaced. Since the 60-minute/24-hour MAM ratio was expressed as a percent, the percent bias and mean absolute error are the given as the bias and MAE in the original percent units (not as a percentage of the percent).

For the 60-minute/24-hour MAM ratio, the overall bias was about 1 percent and the mean absolute error (MAE) less than 4 percent. For the 60-minute, 24-hour, and 10-day MAM intensities, biases were about 2 percent, and the MAE decreased with duration from 9.7 percent at 60-minute duration to 8.8 percent at 10-day duration. Biases for 15-minute to 12-hour durations were similar to those for the 60-minute duration, ranging from 2.0 to 2.2 percent, and MAEs ranging from 8.9 to 10.4 percent. Errors for 2- to 60-day durations were similar to those for the 24-hour and 10-day durations, with biases ranging from 2.1-2.3 percent, and MAEs from 8.5 to 8.9 percent. Given the lack of data at durations of less than 24 hours, one would have expected the 15-minute to 12-hour MAM errors to be substantially higher than those for the 24-hour to 60-day MAMs. A likely reason why this was not the case was that the addition of many synthesized stations, derived from a PRISM interpolation of R24 values, resulted in a station data set that was spatially consistent, and thus, somewhat easier to interpolate with each station deleted from the data set. Therefore, there is little doubt that the true interpolation errors for the 60-minute MAM are higher than those shown in Table 4.

Appendix A.5 Peer review comments and responses

A peer review of preliminary results for the California precipitation frequency project was carried out during an eight week period starting on July 22, 2010. The request for review was sent via email to the over 600 members of the HDSC list-server from all over the United States and other interested parties in California. Potential reviewers were asked to evaluate the reasonableness of point precipitation frequency estimates as well as their spatial patterns. The review included the following items:

1. List of all stations used in the analysis. The list included information on station name, state, source of data, assigned station ID, latitude, longitude, elevation, and period of record. It also showed information if the station was merged with another station, if the station was co-located with another station with a different ID, and if metadata at the station were changed.
2. List of all stations that were received by HDSC, but not considered in analysis. This list contained stations that were not used, either because there was another station with a longer period of record nearby, station data were not reliable, or the station period of record was not long enough and it was not a candidate for merging with any nearby station.
3. At-station depth-duration-frequency curves for a range of durations for which annual maximum series (AMS) data were extracted.
4. Spatially-interpolated maps of mean annual maxima for 60-minute, 24-hour and 10-day durations.
5. Precipitation frequency estimates for 60-minute, 24-hour and 10-day durations and for 2-year and 100-year average recurrence intervals.

Five reviews were received, some of which represented consolidated feedback from several individuals in the same agency. All reviewers' comments and HDSC's responses are shown below. Similar comments were grouped together and are accompanied by a single HDSC response. The comments and their respective HDSC responses have been divided into five categories:

1. Station metadata;
2. At-station precipitation frequency estimates;
3. Precipitation frequency grids/maps;
4. Intensity (or depth)-duration-frequency (IDF or DDF) curves;
5. Web interface.

1. Comments pertaining to station metadata

1.1 Of the roughly 100 rain gage stations listed in the "CA_Metadata_Used.xls" spreadsheet that are within District 11 boundary, 26 gages were identified as "Directly Used" (23 in San Diego Co. & 3 in Imperial Co.) and incorporated into this Atlas. All were found to be accurate regarding their geographic location. I also checked the geographic location of 21 "Directly Used" rain gage stations adjacent to D-11 (3 in Orange Co., 11 in Riverside Co. & 7 in the State of Arizona). One of those stations, in Riverside Co. may be improperly located. The "Eagle Mountain" (Station ID 04-2598) is listed at Longitude -115.4508° but the actual mountain peak by that name is near Longitude -115° 45' 08". Perhaps the gage is accurately located and the name is the only nearby reference but it seems like it's misplaced?

HDSC response: We investigated the location of Eagle Mountain station. Both the geographic location and the name of the station are correct. The name of the station is a reference to Eagle Mountain Road, not to the Eagle Mountain Peak that, as the reviewer correctly points out, is at a different location.

1.2 We have imported the rain gauges into GIS to compare your coordinates (lat, long) to our active gauges [Contra Costa County]. We find that many of them do not line up well (see attached example). Please confirm that we should be using the GCS_North_American_1983 geographic coordinate system?...

The lat/long values you have are different than what we provided... We would like clarification on how the lat/long values were used and what precision you used... Understanding the geographic projections will help me provide better feedback/confirmation on the station locations. 1. What geographic projection did you assume our lat/long values were in? 2. What geographic projection are your lat/long values in?...

Your spreadsheet shows some stations in our county as being sourced by other counties…. The Alameda County stations could be in our County due to lat/long errors or they could be attributed to the wrong county. For example the one gage that plots near Lafayette reservoir (LAFRES_122, 81-0068 , is likely managed by East Municipal Utility District (HQ in Alameda County?), but the source says Alameda County. There is one station in our county that says the source is Santa Clara County. We cannot readily verify the locations of the NCDC or RAWS stations.

HDSC response: Yes, we used the GCS_North_American_1983 geographic coordinate system. We found and corrected an error in our conversion of the metadata coordinates for the Contra Costa County stations. We rechecked metadata information for all stations used in our analysis.

In our metadata table, the source field indicated who provided the data, not necessarily who maintained the station. Alameda County provided some stations that are located in Contra Costa County and the location of these stations was verified by them.

2. Comments pertaining to at-station precipitation frequency estimates

2.1 Looking at some locations where precipitation gages exist, we see changes between NOAA14 and NOAA Atlas 2 that seem reasonable; however, other locations are of great concern! We created a table [a relevant excerpt is shown in Table A.5.1] to show our random sampling. The table compares the NOAA14 100-yr estimates with three other sources 1. Jim Goodridge's Regional [Precipitation] Study for CA Dep Water Resources 2. NOAA Atlas 2 3. HMR 59, Probable Maximum [Precipitation] for California, NOAA. The locations we sampled shown in yellow are of concern.

We are able to derive estimates of extreme events (200yr, 500yr, 1000yr, 10,0000 yr from NOAA Atlas 2 by using a formula. While we acknowledge that NOAA Atlas 2 was not derived to estimate values of those extreme events, it gives us a feeling for how a big a change were seeing with the NOAA14 estimates. …[We used] a formula to extrapolate the Gumbel frequency curve since the Gumbel frequency curve is a straight line on Gumbel paper.… In some of these, the NOAA14 estimates exceed or equal the 10,000 yr event estimate from NOAA Atlas 2. Also, for the first station (Johnsondale), the new NOAA14 100YR depth is getting close to the Probable Maximum Precipitation from HMR 59. Sacramento District of the Corps is currently studying the Kern River. The top six gages in our spreadsheet (Johnsondale thru Weldon) are located in

this region. In December 1966, a real extreme storm hit this area. Some gages recorded precipitation that approached the estimated Probable Maximum Precipitation for that area. …[It was] said that the NWS updated the PMP because of this event.

Table A.5.1. Excerpt from peer reviewer's table comparing 100-year 24-hour estimates from previous work by Jim Goodridge, NOAA Atlas 2 (NA2), probable maximum precipitation (PMP) from HMR 59 and NOAA Atlas 14 (NA14).

	Lat	Long	Elev	Record length	Goodridge 100-yr	NA 2 100-yr	HMR 59 PMP	NA14 100-yr	% Diff NA2 to NA14

Success Dam	36.058	-118.918	590	49	3.53	4.00	10.4	3.7	-8%

HDSC response: We have carefully investigated the stations with the largest differences between NOAA Atlas 14 and NOAA Atlas 2 precipitation frequency estimates for data quality and appropriate regionalization, including in the area along Kern River. Subsequent regionalization and quality control efforts after the peer review lowered the NOAA Atlas 14 frequency estimates for the stations of concern. However, considerable differences remain between the NOAA Atlas 2 and final NOAA Atlas 14 estimates at few locations, especially for longer average recurrence intervals. The new estimates are based on up to 40 more years of data than those published in NOAA Atlas 2 and improved analysis techniques, so we are confident in these final estimates.

Johnsondale and Isabella Dam, where substantial differences still remain, have had major precipitation/flood events occurring since 1966: the Great Flood of 1966 and the November flood of 2002. 24-hour precipitation amounts measured during those two events far exceeded the NOAA Atlas 2 100-year, 24-hour estimate of 4.46 inches at Isabella Dam. In fact, Johnsondale has had four 24-hour events since 1963 that exceeded the 100-year estimate of 8.15 inches from

NOAA Atlas 2 when adjusted for constrained observations (7.35 inches in 1963, 15 inches in 1966, 12.38 inches in 2002, 8 inches in 2010).

2.2 …based on a study performed by [a commercial contractor], the 100-year depth at the Petaluma Fire Station is 5.40 inches in 24 hr. Analysis was based on 98 years of data, including the 1982 storm depth of 6.4 inches and with the interval correction factor of 1.14. Therefore, the NOAA estimate of 6.37 inches appears to be too high (even higher than the revised 500-year depth of 6.35 inches)….City of Santa Rosa: 100-yr, 24 hr event is 5.2 inches. There will be an inch increase in these areas and will have significant impact on floodplain and risk mitigation for these communities.

HDSC response: Annual maximum series for Petaluma Airport (04-6826) and Petaluma Fire Station (84-6833) stations have 95 years and 60 years of data, respectively. An unconstrained 24-hour amount of 6.4 inches from the 1982 event is included in both series. Based on empirical distributions, 100-year estimates for these stations should be above 6 inches. We re-examined at-station precipitation frequency estimates and their spatial patterns for the area for 100-year ARI and we think that the final 100-year, 24-hour estimate of 6.12 inches at Petaluma is reasonable.

Similarly, Santa Rosa (04-7965) station has 103 years of annual maximum data with a maximum 1-day rainfall of 5.23 inches. We investigated probability plots for different distributions for this location as well as spatial patterns for 100-year 24-hour estimates in this area; the final 100-year 24-hour estimate of 5.8 inches seems reasonable.

2.3 Peak isopluvial lines for the Lost Coast area and Smith River canyon are in slightly different locations from previous version. I cannot tell if this is based on additional information, mapping techniques or spatial smoothing.

HDSC response: An additional 40 years of data and a much denser network of gauged locations were available for this project. In addition, quality control, frequency analysis, and spatial interpolation techniques have improved since the previous publication. Please refer to our documentation (Section 7) for analysis of the differences in precipitation frequency estimates between the two NOAA Atlases.

2.4 As for the rain gage data itself, in general the District 11 distribution looks appropriate. Specifically, I compared each of the gages in San Diego County… The peak isopluvial in San Diego Co. had previously been this Cuyamaca (Station ID 04-2239) Gage with the Palomar (Station ID 04-6657) Gage the 2nd highest. The data presented here has decreased the Cuyamaca data, as stated above, by about 30% and increased the Palomar data by about 35% so that now the Palomar Station is the peak location. This may indeed be accurate although the MAM 60-minute map looks like the peak, for this duration, may still be at the Cuyamaca Station location.

HDSC response: We have carefully investigated at-station frequency estimates and the spatial contours around the two peaks (Palomar and Cuyamaca stations). Based on the available data, an average annual maximum is higher for sub-daily durations at the Palomar peak and it is higher for daily durations at the Cuyamaca peak. However, the differences in precipitation frequency estimates for these two locations are small and it is unclear if they are due to a natural phenomenon or they can be attributed to the uncertainty in the data and estimation methods.

2.5 Of the Arizona rain gage stations that border District 11, I'm not too familiar with the rainfall patterns but on the surface it does seem that the Kofa Mine (Station ID 02-4702) gage rainfall amounts are considerably higher than a number of gages in the nearby vicinity.

HDSC response: Annual maximum series data for Kofa Mine (02-4702) station has been thoroughly checked for high outliers and quality of data. In addition, Kofa Mine, located in Arizona, was not assigned to final region of any California station, so it did not influence precipitation frequency estimates for any station in California.

2.6 We are wondering if your procedure for estimating Precipitation Frequency is somehow not correctly adjusting for HIGH OUTLIERS? This might explain why some locations in this region [along the Kern River] have huge changes in depths for the 100yr event since the 1966 storm might be causing a drastic change in statistics for this area.

HDSC response: We investigated and thoroughly scrutinized high outliers at all stations for all durations. Any inconsistencies in results that arose from a station that captured an extreme event coupled with a short record length were also carefully investigated and, if appropriate, the station in question was removed from the dataset. In addition, the regional approach based on L-moments that was used in this project is particularly robust to outliers.

2.7 We have looked at one station (Rodeo Fire 85-0013) and plotted our local standard information over it. … In general, the PFD curves provide higher storm amounts for the shorter duration storms and lower storm amounts for the longer duration storms....We would like to know what procedure or software you used to create your PFD curves so that we can better compare your results to ours.

HDSC response: The regional approach based on L-moment statistics used in this project is described in Section 4 of this document.

3. Comments pertaining to precipitation frequency grids/maps

3.1 … precipitation frequency estimates for Marin County are suspect and severely lacking the geospatial variability that would be expected given the county's coastal location and topography, which result in [topographically] enhanced rainfall. Data that we have collected (and submitted for the purposes of your update) better reflect this variability. I feel that the three data points in the county used to arrive at the Atlas 14 IDF estimates are not sufficient for providing a useful product. Two of these sites are within close proximity of one another and none are along either the Pacific or Bay coasts.

HDSC response: Prior to the peer review, several stations in the area did not meet the minimum requirement for data years and so were not used in the analysis. After the review, the user provided annual maximum series data that greatly increased the station density in the area and improved the resolution of spatial characteristics in the area. Updated estimates much better reflect expected spatial patterns.

3.2 …It is difficult to review the color ramp versions of these maps. When the colors are made somewhat transparent to allow for the "landforms" to show through, the resulting shades (intensities) are not easy to discern, especially for someone like me who has difficulty differentiating within certain color groups in general. I personally prefer "contour-like" maps for value extraction but do appreciate the color ramp versions for general "tendency-like" regional displays.

HDSC response: Cartographic maps were created to serve as visual aids and are not recommended for estimating precipitation frequency estimates. Users are advised to take advantage of the PFDS interface or the underlying ASCII grids for obtaining precipitation frequency estimates.

3.3 Maps: Using a larger color square in the key may make it easier to determine which color matches the coloring in the map. The colors don't seem to match quite right.

HDSC response: This was corrected in the final maps.

4. Comments pertaining to the IDF or DDF curves

4.1 In the past we've felt that the Imperial County (Desert Region) intensity values given in the IDF32 and previous versions, were not reflective of the high intensity, short duration storm characteristics that the region experiences. We had directions in our drainage guidelines to design "on-site" facilities considering the 100-year storm intensities and tried to persuade our designers to use these values, if economically and functionally practical. Since the NOAA Atlas 14 application has been available we've noticed that (on the couple of projects that we've had in the desert region) the NOAA 25-year intensity values do indeed compare favorably to the previous IDF program's 100-year values. So, we've been comfortable with the Atlas 14 values (lack of equations, aside) and have been eagerly anticipating the release of this Coastal region application (if we can get the equations incorporated, or method to develop them standardized.) So thanks for your participation and coordination efforts on this project. It will hopefully be a great tool that can be easy to use, accessible to all and we'll have the comfort of knowing that it was developed by the rainfall estimation experts.

HDSC response: We do not provide IDF curves in analytical form as analytical fitting could potentially significantly alter estimates. However, if desired, one can use the values from the IDF table to develop an IDF analytical equation.

4.2 IDF curves: Could the curve equation be displayed? (Engineers like exact numbers even if they shouldn't be.) This is still a point IDF whereas IDF2000 interpolates for us, making life easier. If I could get an interpolated IDF curve by clicking on the map at the location of my watershed, it would be more useful.

HDSC response: See response in 4.1.

4.3. Although the graphs themselves and the tech notes on the Atlas 14 website indicate these IDF relationships cannot be represented by a single equation, the practicality of its use would warrant

a procedure for developing an equation to use or a procedure to develop such an equation between values that appear in the table. This is needed for studies where the duration/rainfall intensity is continually being recalculated as the storm runoff amount is routed through the drainage basin. The concern again is, consistency and reproducibility, such that two users with the same chart or table can, to an adequate level of detail, arrive at the same rainfall value. This lends to the credibility of the final study results.

HDSC response: See response in 4.1.

4.4 We noticed there is no 72-hour depth. We realize that the 72-hr depth was not done for NOAA Atlas 14 in Nevada, but we feel this is a critical duration in California. Our design storms are usually balanced to this duration and this duration may determine whether a dam spills or not. A linear interpolation between the 48-hour and the 96-hour depths will result in an inaccurate 3-day depth (3-day depth being too small). If there is a way to obtain this estimate, it would be greatly appreciated.

HDSC response: Per this request, we added 3-day duration to the final set of durations for which precipitation frequency estimates are calculated.

4.5 All of the rain gage Depth-Duration-Frequency charts in the peer review portal have a curve for the "20-yr" return period whereas the Atlas 14 provides a "25-yr" return period graph and table. A good portion of our studies (on-site drainage design) require the 25-yr return period values. Hopefully this value will be included in the final version of this application.

HDSC response: Final depth-duration-frequency tables and plots include the 25-year average recurrence interval.

4.6 The charts and graphs in the output are not detailed enough to provide consistently reproducible value extractions. Two users may estimate different values, for rainfall intensity for example, from the same graph, or if two users interpolate differently (linear vs. logarithmic) between values in the table.

HDSC response: We provide estimates for a wide range of frequencies and durations. However, if interpolation between given values is necessary, while different interpolation methods will produce slightly different estimates, the differences will be well within the confidence limits of the estimates.

5. Comments pertaining to the web interface

5.1 Interactive map: the "mouse-over" is very sensitive, hard to exactly hover over the station. When finally hovering appropriately, a pop-up next to the cursor with the station name would be more user-friendly than displaying on the side.

HDSC response: This issue was corrected.

5.2 A zoom-in button would be appreciated, similar to the peer review "5. At-Station" rain gage selection map, so that as you zoom closer, more location details appear, in order to select (click on) a specific point more accurately. Previously Atlas 14 displayed (in the output) a nice location map showing where the point location was selected. That appears to have been replaced with a link to a mapping webpage but has no "flag" or point location identified that I can see, in the current version. This was good for the review verification process whereas now the chosen Lat/Long will have to be located on a map to verify the correctness of the chosen "project" location.

HDSC response: The web pages have been updated with the publication of Volume 6 and include zooming in functionality from Google Maps© to allow precision when selecting a location.

Appendix A.6 Temporal distributions of annual maxima

1. Introduction

Temporal distributions of annual maxima are provided for 6-, 12-, 24-, and 96-hour durations. The temporal distributions are expressed in probability terms as cumulative percentages of precipitation totals at various time steps. To provide detailed information on the varying temporal distributions, separate temporal distributions were also derived for four precipitation cases defined by the duration quartile in which the greatest percentage of the total precipitation occurred.

Stations were grouped into fourteen climate regions, shown in Figure A.6.1, and separate temporal distributions were derived for each climate region. Regions were delineated based on extreme precipitation characteristics expressed through 24-hour mean annual maximum (MAM) estimates, mean annual precipitation (MAP), elevation, latitude, and proximity to the coast. In some cases, transitional regions were created between very distinct climate regions.

Climate regions. Some of the highest precipitation amounts occur in region 1, where precipitation is orographically enhanced by the western facing Coastal Range Mountains as moisture-laden storms reach the shoreline. In transitional region 2 which is more inland, the elevation increases slightly, but as it is farther from the coast, precipitation amounts begin to decrease. To the south, region 7 is also influenced by the Coastal Range, but the terrain is not as varied and precipitation amounts are lower due to the stronger influence of the eastern Pacific high pressure that forces maritime storms to the north especially during the summer. Region 8 is a drier transitional region due to its leeward proximity to the Coastal Range.

Beyond these mountains, the low-lying interior Central Valley regions (5, 9 and 10) are cut off from the maritime moisture and receive much less precipitation. The more northern region 5 has relatively higher precipitation amounts than regions 9 and 10. Region 9 contains some of the lowest precipitation amounts in the state. MAP and MAM begin to increase in the transitional region 10 and then peak in the Sierra Nevada Range (regions 6 and 11). Region 6 may have lower elevations than region 11, but because it is farther north, it receives increased amounts of precipitation. In northeastern region 3, elevations remain high due to the Cascade Range and Sierra Nevada Range, but leeward characteristics relative to the moisture flow cause it to be a transitional zone into the lower precipitation amounts of region 4 which is part of North America's Great Basin.

In the south, region 12 comprises the LA Basin encircled by a series of mountains that stretch from west to east. This region has the highest precipitation amounts in southern California. Region 13 in southwest California along the coast is flanked by mountains on its northern and eastern sides but the region is so far south that it is impacted by fewer storms. The Cascade Range, Sierra Nevada and LA Basin mountains serve to cut off moisture to eastern California forming a very dry, desert climate particularly in the southeast (region 14). However, the southeastern desert region is susceptible to the Mexican Monsoon during the summer months where tropical Pacific moisture flows up from the southwest triggering brief but heavy downpours especially at higher elevations.

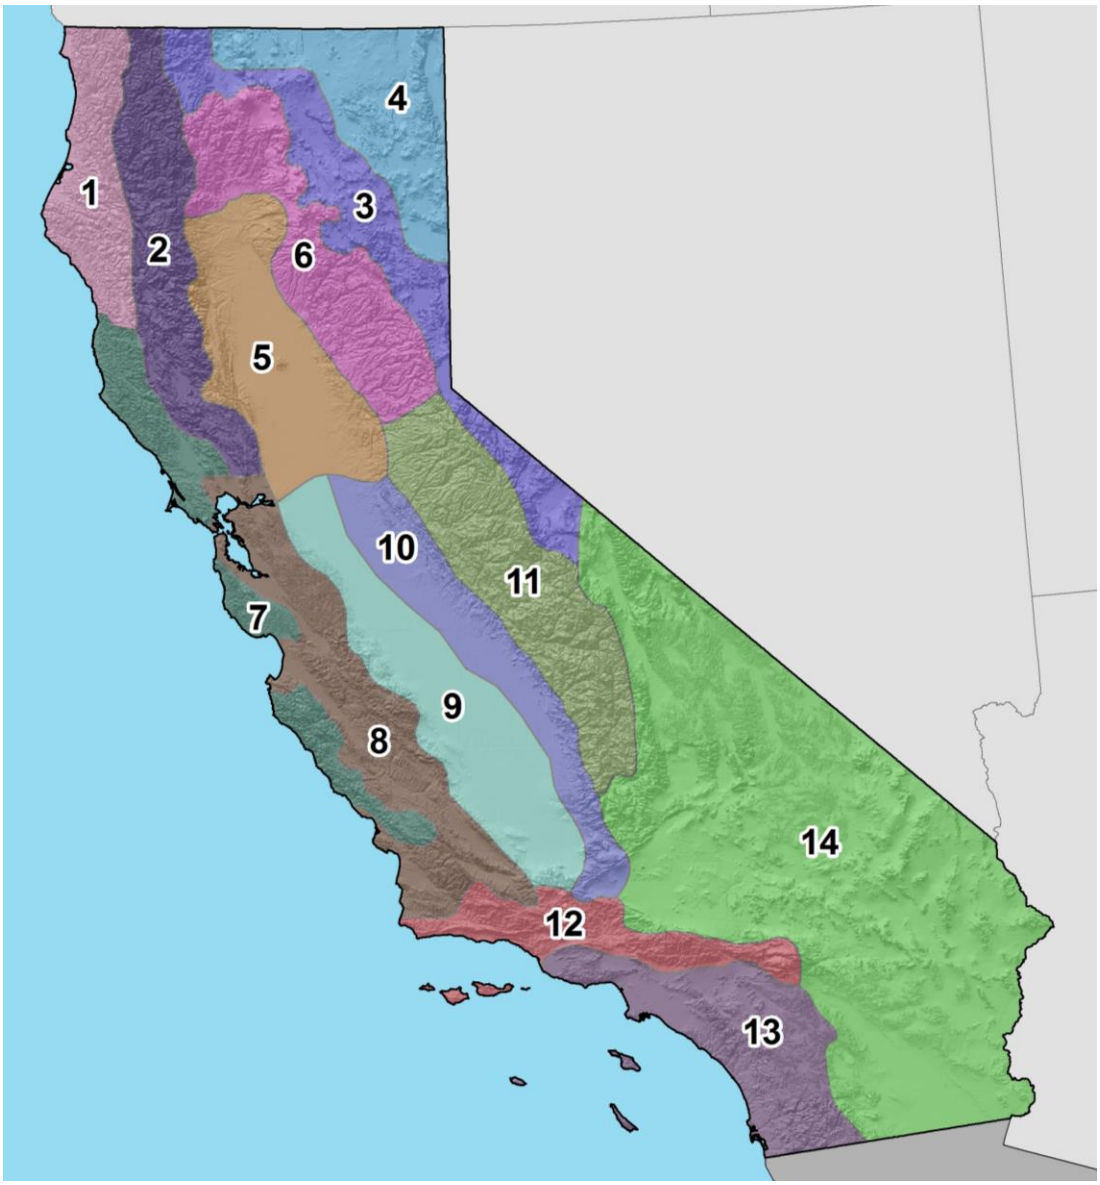

Figure A.6.1. Climate regions used for temporal distribution and seasonality analyses.

2. Methodology and results

The methodology used to produce the temporal distributions is similar to the one developed by Huff (1967) except in the definition of precipitation cases. In accordance with the way a precipitation case ('event') was defined for the precipitation frequency analysis, a precipitation case for the temporal distribution analysis was computed as the total accumulation over a specific duration (6-, 12-, 24-, or 96-hours). As a result, it may contain parts of one or more storms. Because of that, temporal distribution curves presented here may be different from corresponding temporal distribution curves obtained from the analysis of single storms.

Also, precipitation cases for this project always start with precipitation but not necessarily end with precipitation resulting in potentially more front-loaded cases when compared with distributions derived from the single storm approach. To reduce biases, a constraint was imposed to exclude cases with a

continuous dry period that lasted for more than 30% of the duration. This restriction produced a less variant sample. By imposing the restriction on continuous dry periods, the number of cases available for temporal distribution analysis decreased with duration because long, continuous precipitation events occurred less frequently than continuous short-duration events. Cases were selected from the annual maximum series at each station. Table A.6.1 shows the total number of precipitation cases and number of cases in each quartile for each region for each selected duration.

For each precipitation case, cumulative precipitation amounts were converted into percentages of the total precipitation amount at one hour time increments. All cases for a specific duration were then combined and probabilities of occurrence of precipitation totals were computed at each hour. The temporal distribution curves for nine deciles (10% to 90%) were smoothed using linear programming method (Bonta and Rao, 1988) and plotted in the same graph. Figure A.6.2 shows as an example of temporal distribution curves for the four selected durations for region 13; time steps were converted into percentages of durations for easier comparison.

The cases were further divided into four categories by the quartile in which the greatest percentage of the total precipitation occurred. Table A.6.1 shows the numbers and proportion of precipitation cases used to derive the temporal distributions in each quartile. Unlike the cases of 12-, 24-, and 96-hour durations in which the number of data points can be equally divided by four, the cases of 6-hour duration contain only six data points and they cannot be evenly distributed into four quartiles. Therefore, in this analysis, for 6-hour duration, the first quartile contains precipitation cases where the most precipitation occurred in the first hour, the second quartile contains precipitation cases where the most precipitation occurred in the second and third hours, the third quartile contains precipitation cases where the most precipitation occurred in the fourth hour, and the fourth quartile contains precipitation cases where the most precipitation occurred in the fifth and sixth hours. This uneven distribution affects the number of cases contained in each quartile for the 6-hour duration. Figures A.6.3 through A.6.6 show the temporal distribution curves for four quartile cases for 6-hour, 12-hour, 24-hour and 96-hour durations, respectively.

Table A.6.1. Total number of precipitation cases and number (and percent) of cases in each quartile for selected durations for each designated climate region.

Duration	Region	All cases	First-quartile cases	Second-quartile cases	Third-quartile cases	Fourth-quartile cases
6-hour	1	424	66 (16%)	117 (28%)	149 (35%)	92 (22%)
	2	573	80 (14%)	177 (31%)	177 (31%)	139 (24%)
	3	583	107 (18%)	182 (31%)	168 (29%)	126 (22%)
	4	274	57 (21%)	82 (30%)	91 (33%)	44 (16%)
	5	883	143 (16%)	240 (27%)	313 (35%)	187 (21%)
	6	968	173 (18%)	241 (25%)	297 (31%)	257 (27%)

	14	384	137 (36%)	109 (28%)	94 (24%)	44 (11%)
96-hour	1	350	111 (32%)	91 (26%)	87 (25%)	61 (17%)
	2	425	118 (28%)	126 (30%)	101 (24%)	80 (19%)
	3	316	100 (32%)	90 (28%)	81 (26%)	45 (14%)
	4	125	38 (30%)	37 (30%)	25 (20%)	25 (20%)
	5	497	177 (36%)	120 (24%)	114 (23%)	86 (17%)
	6	681	197 (29%)	155 (23%)	178 (26%)	151 (22%)
	7	477	170 (36%)	123 (26%)	102 (21%)	82 (17%)
	8	727	265 (36%)	170 (23%)	201 (28%)	91 (13%)
	9	128	43 (34%)	27 (21%)	31 (24%)	27 (21%)
	10	134	32 (24%)	36 (27%)	35 (26%)	31 (23%)
	11	431	157 (36%)	108 (25%)	115 (27%)	51 (12%)
	12	356	123 (35%)	66 (19%)	93 (26%)	74 (21%)
	13	583	219 (38%)	106 (18%)	128 (22%)	130 (22%)
	14	95	38 (40%)	18 (19%)	22 (23%)	17 (18%)

From the Precipitation Frequency Data Server, regional temporal distribution data are available in a tabular form for a selected location under the 'Supplementary information' tab or through the temporal distribution web page (http://hdsc.nws.noaa.gov/hdsc/pfds/pfds_temporal.html). For 6-, 12- and 24-hour durations, temporal distribution data are provided in 0.5-hour increments and for 96-hour duration in hourly increments.

3. Interpretation

Figure A.6.2 shows as an example the temporal distribution curves of all precipitation cases in region 13 for the 6-, 12-, 24-, and 96-hour durations. Time steps were converted into percentages of total durations for easier comparison. Figures A.6.3 through A.6.6 show temporal distribution curves for first-, second-, third-, and fourth-quartile cases for 6-hour, 12-hour, 24-hour and 96-hour durations, respectively. First-quartile plots show temporal distribution curves for cases where the greatest percentage of the total precipitation fell during the first quarter of the duration (e.g., the first 3 hours of a 12-hour duration). The second, third, and fourth quartile plots are similarly for cases where the most precipitation fell in the second, third, or fourth quarter of the duration.

The temporal distribution curves represent the averages of many cases and illustrate the temporal distribution patterns with 10% to 90% occurrence probabilities in 10% increments. For example, the 10% curve in any figure indicates that 10% of the corresponding precipitation cases had distributions that fell above and to the left of the curve. Similarly, 10% of the cases had temporal distribution falling to the right and below the 90% curve. The 50% curve represents the median temporal distribution.

The following is an example of how to interpret the results using the figure (a) in the upper left panel of Figure A.6.5 for 24-hour first-quartile cases in region 13.

- In 10% of the first-quartile cases, 50% of the total precipitation fell in the first 4.3 hours (18% of duration) and 90% of the total precipitation fell by 12 hours (50% of duration).
- A median case of this type will drop half of the precipitation (50% on the y-axis) in approximately 6.2 hours.
- In 90% of the cases, 50% of the total precipitation fell by 10.6 hours (44% of duration) and 90% of precipitation fell by 22 hours (92% of duration).

Temporal distribution curves are provided in order to show the range of possibilities. Care should be taken in the interpretation and use of temporal distribution curves. For example, the use of different temporal distribution data in hydrologic models may result in very different peak flow estimates. Therefore, they should be selected and used in a way to reflect users' objectives.

Appendix A.7 Seasonality

1. Introduction

To portray the seasonality of extreme precipitation throughout the project area, annual maxima that exceeded precipitation frequency estimates (quantiles) with selected annual exceedance probabilities (AEPs) for chosen durations were examined for each climate region described in Appendix A.6. Graphs showing the monthly variation of the exceedances for a region are provided for each location in the project area via the Precipitation Frequency Data Server (PFDS) at http://hdsc.nws.noaa.gov/hdsc/pfds/. For a selected location, seasonal exceedance graphs can be viewed by selecting 'V. Seasonality analysis' of the 'Supplementary information' tab on the output page.

2. Method

Separate seasonal exceedance graphs were created for each of fourteen climate regions. They show the percentage of annual maxima for a given duration from all stations in a region that exceeded corresponding precipitation frequency estimates at selected AEP levels in each month. Results are provided for unconstrained 60-minute, 24-hour, 2-day, and 10-day durations and for annual exceedance probabilities of 1/2, 1/5, 1/10, 1/25, 1/50, and 1/100.

To prepare the graphs, first, the number of annual maxima exceeding the precipitation frequency estimate at a station for a given AEP was tabulated for each duration. Those numbers were then combined for all stations in a given region, sorted by month, normalized by the total number of data years in the region, and finally plotted via the PFDS.

3. Results

The exceedance graphs for a selected location (see an example for a location in region 9 in Figure A.7.1) indicate percent of annual maxima exceeding the quantiles with selected AEPs for various durations. The percentages are based on regional statistics. On average, 1 % of annual maxima for a given duration in a year (i.e., the sum of percentages of all twelve months) are expected to exceed the 1/100 AEP quantile, 4% is expected to exceed the 1/25 AEP quantile, etc.

Note that seasonality graphs are not intended to be used to derive seasonal precipitation frequency estimates.

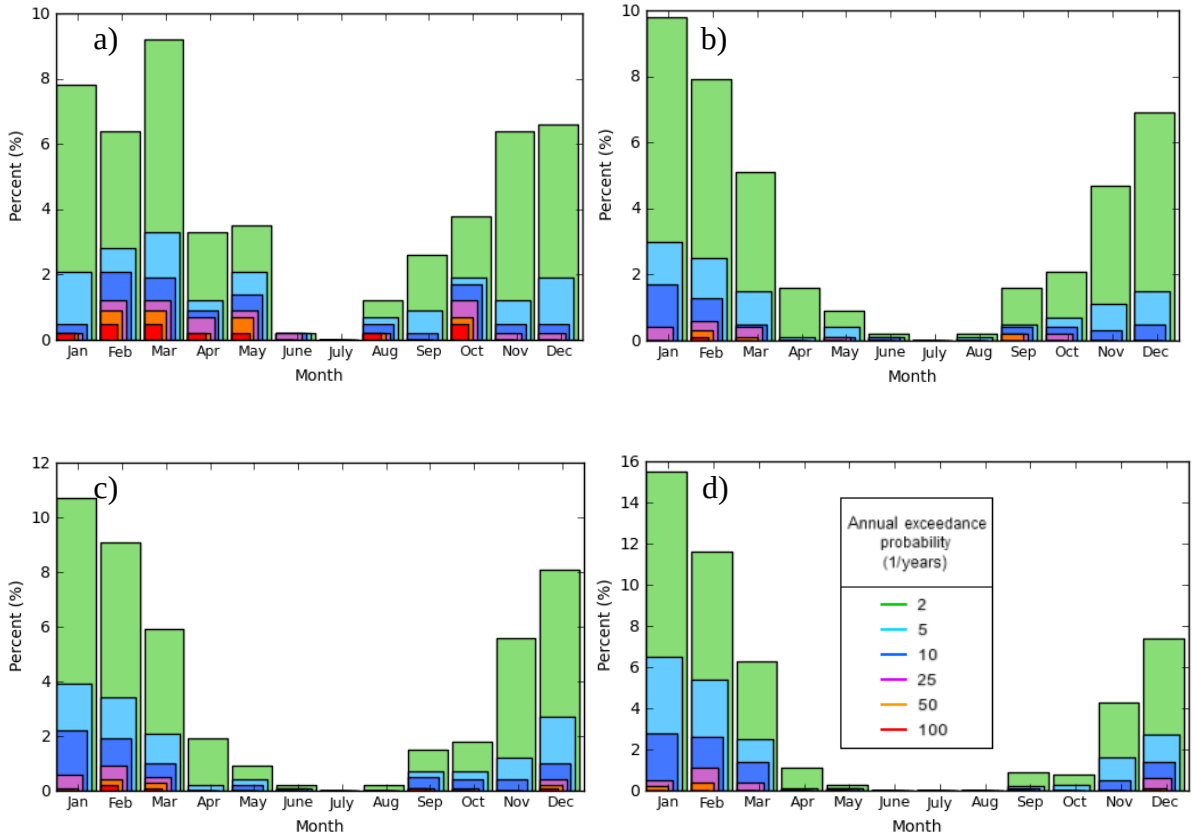

Figure A.7.1. Example of seasonal exceedance graphs for region 9 for the: a) 60-minute, b) 24-hour, c) 2-day, and d) 10-day durations.

Glossary

(All definitions are given relative to precipitation frequency analyses in NOAA Atlas 14 Volume 6)

ANNUAL EXCEEDANCE PROBABILITY (AEP) – The probability associated with exceeding a given amount in any given year once or more than once; the inverse of AEP provides a measure of the average time between years (and not events) in which a particular value is exceeded at least once; the term is associated with analysis of annual maximum series (see also AVERAGE RECCURENCE INTERVAL).

ANNUAL MAXIMUM SERIES (AMS) – Time series of the largest precipitation amounts in a continuous 12-month period (calendar or water year) for a specified duration at a given station.

ASCII GRID – Grid format with a 6-line header, which provides location and size of the grid and precedes the actual grid data. The grid is written as a series of rows, which contain one ASCII integer or floating point value per column in the grid. The first element of the grid corresponds to the upper-left corner of the grid.

AVERAGE RECURRENCE INTERVAL (ARI; a.k.a. RETURN PERIOD, AVERAGE RETURN PERIOD) – Average time between *cases of a particular precipitation magnitude* for a specified duration and at a given location; the term is associated with the analysis of partial duration series. However, ARI is frequently calculated as the inverse of AEP for the annual maximum series; in this case it represents the average period between years in which a given precipitation magnitude is exceeded at least once.

CASCADE, RESIDUAL ADD-BACK (CRAB) – The HDSC-developed spatial interpolation procedure for deriving grids of precipitation frequency estimates from grids of mean annual maxima and point precipitation frequency estimates for a given duration.

CONSTRAINED OBSERVATION – A precipitation measurement or observation bound by clock hours and occurring in regular intervals. This observation requires conversion to an unconstrained value (see UNCONSTRAINED OBSERVATION) because maximum 60-minute or 24-hour amounts seldom fall within a single hourly or daily observation period.

DATA YEARS – See RECORD LENGTH.

DEPTH-DURATION-FREQUENCY (DDF) CURVE – Graphical depiction of precipitation frequency estimates in terms of depth, duration and frequency (ARI or AEP).

DISTRIBUTION FUNCTION (CUMULATIVE DISTRIBUTION FUNCTION) – Mathematical description that completely describes frequency distribution of a random variable, here precipitation. Distribution functions commonly used to describe precipitation data include 3-parameter distributions such as Generalized Extreme Value (GEV), Generalized Normal, Generalized Pareto, Generalized Logistic and Pearson type III, the 4-parameter Kappa distribution, and the 5-parameter Wakeby distribution.

FEDERAL GEOGRAPHIC DATA COMMITTEE (FGDC) COMPLIANT METADATA – A document that describes the content, quality, condition, and other characteristics of data and follows the guidelines set forth by the FGDC; metadata is “data about data.”

FREQUENCY – General term for specifying the average recurrence interval or annual exceedance probability associated with specific precipitation magnitude for a given duration.

FREQUENCY ANALYSIS – Process of derivation of a mathematical model that represents the relationship between precipitation magnitudes and their frequencies.

FREQUENCY ESTIMATE – Precipitation magnitude associated with specific average recurrence interval or annual exceedance probability for a given duration.

HEAVY PRECIPITATION – Precipitation with an average recurrence interval roughly between 1 year and 1,000 years for a given duration.

INTENSITY-DURATION-FREQUENCY (IDF) CURVE – Graphical depiction of precipitation frequency estimates in terms of intensity, duration and frequency.

INTERNAL CONSISTENCY – Term used to describe the required behavior of the precipitation frequency estimates from one duration to the next or from one frequency to the next. For instance, it is required that the 100-year 3-hour precipitation frequency estimates be greater than (or at least equal to) corresponding 100-year 2-hour estimates.

L-MOMENTS – L-moments are summary statistics for probability distributions and data samples. They are analogous to ordinary moments, providing measures of location, dispersion, skewness, kurtosis, and other aspects of the shape of probability distributions or data samples, but are computed from linear combinations of the ordered data values (hence the prefix L).

MEAN ANNUAL PRECIPITATION (MAP) – The average precipitation for a year (usually calendar) based on the whole period of record or for a selected period (usually 30 year period such as 1971-2000).

PARTIAL DURATION SERIES (PDS) – Time series that includes all precipitation amounts for a specified duration at a given station above a pre-defined threshold regardless of year; it can include more than one event in any particular year.

PRECIPITATION FREQUENCY DATA SERVER (PFDS) – The on-line portal for all NOAA Atlas 14 deliverables, documentation, and information; http://hdsc.nws.noaa.gov/hdsc/pfds/.

PARAMETER-ELEVATION REGRESSIONS ON INDEPENDENT SLOPES MODEL (PRISM) – Hybrid statistical-geographic approach to mapping climate data developed by Oregon State University's PRISM Climate Group.

QUANTILE – Generic term to indicate the precipitation frequency estimate associated with either ARI or AEP.

RECORD LENGTH – Number of years in which enough precipitation data existed to extract meaningful annual maxima in a station's period of record (or data years).

UNCONSTRAINED OBSERVATION – A precipitation measurement or observation for a defined duration. However the observation is not made at a specific repeating time, rather the duration is a moveable window through time.

WATER YEAR – Any 12-month period, usually selected to begin and end during a relatively dry season. In NOAA Atlas 14 Volume 6, it is defined as the period from October 1 to September 30.
